

Practical Asymptotics (App Topic C)

Andrew Martin

May 22, 2019

0.1 Introduction

This course looks into finding ‘approximately analytic’ solutions - this will be like truncating Taylor series kinda stuff afaik.

In practice we will use this to make the approximately analytic solutions and then apply it to computation for numerical solutions. We will develop a tool-kit of asymptotic techniques and apply them to real-world modelling problems. The plan is:

- Intro to asymptotics
- Perturbation/asymptotic methods
- Boundary layer theory and asymptotic matching
- Multiscale methods and homogenisation theory
- TBD probably asymptotic approximation of integrals or asymptotics beyond-all-orders

0.2 Introduction to asymptotics

0.2.1 Fun example:

Here's a ‘difficult problem’:

Let's find the real solution to the quintic equation

$$x^5 + x = 1$$

We know that there are 5 roots since x^5 is the highest power (some of which are probably complex). There are no exact solutions for these roots (only works up to x^4). We could easily solve this numerically, but another approach is to consider a related problem:

$$x^5 + \epsilon x = 1$$

Where the parameter ϵ will be small (and to go back to the previous equation we have to set $\epsilon = 1$).

Denote the real root $x = a(\epsilon)$. Where $a(\epsilon = 1)$ will be the solution to the original equation. This is a ‘perturbation’ problem, it features a parameter which when set to 0 is easily solvable. We care about when $\epsilon \neq 0$ however. Set $\epsilon = 0$:

$$\begin{aligned} x^5 + 0(x) &= 1 \\ a_0^5 &= 1 \implies a_0 = 1 \end{aligned}$$

Perturbation series (ansatz)

$$\begin{aligned} a(\epsilon) &= \sum_{n=0}^{\infty} a_n \epsilon^n \\ &= a_0 + \epsilon a_1 + \epsilon^2 a_2 + \dots \\ &= 1 + \epsilon a_1 + \epsilon^2 a_2 + \epsilon^3 a_3 + \dots \end{aligned}$$

Sub this series into the equation we want to solve:

$$x^5 + \epsilon x = 1$$

$$(1 + \epsilon a_1 + \epsilon^2 a_2 + \epsilon^3 a_3 + \dots)^5 + \epsilon (1 + \epsilon a_1 + \epsilon^2 a_2 + \epsilon^3 a_3 + \dots) = 1$$

Expanding the 5th power use the binomial theorem, i.e.

$$(A + B)^5 = A^5 + 5A^4B + 10A^3B^2 + 10A^2B^3 + 5AB^4 + B^5$$

$$\begin{aligned} & (1 + \epsilon a_1 + \epsilon^2 a_2 + \epsilon^3 a_3 + \dots)^5 \\ &= (1 + \epsilon(a_1 + \epsilon a_2 + \epsilon^2 a_3 + \dots))^5 \\ &= (1 + 5\epsilon(a_1 + \epsilon a_2 + \epsilon^2 a_3 + \dots) \\ &+ 10\epsilon^2(a_1 + \epsilon a_2 + \epsilon^2 a_3 + \dots)^2 \\ &+ 10\epsilon^3(a_1 + \epsilon a_2 + \epsilon^2 a_3 + \dots)^3 \\ &+ 5\epsilon^4(a_1 + \epsilon a_2 + \epsilon^2 a_3 + \dots)^4 \\ &+ \epsilon^5(a_1 + \epsilon a_2 + \epsilon^2 a_3 + \dots)^5) \\ &= 1 + \epsilon(5a_1) + \epsilon^2(5a_2 + 10a_1^2) + \epsilon^3(5a_3 + 20a_1a_2 + 10a_2^2) + \dots \end{aligned}$$

Which means:

$$\begin{aligned} 1 + \epsilon(5a_1) + \epsilon^2(5a_2 + 10a_1^2) + \epsilon^3(5a_3 + 20a_1a_2 + 10a_2^2) + \dots + \epsilon(1 + \epsilon a_1 + \epsilon^2 a_2 + \epsilon^3 a_3 + \dots) &= 1 \\ \epsilon(5a_1 + 1) + \epsilon^2(5a_2 + 10a_1^2 + a_1) + \epsilon^3(5a_3 + 20a_1a_2 + 10a_2^2 + a_2) + \dots &= 0 \end{aligned}$$

Equating powers:

$$\epsilon^n \text{ gives: } \begin{cases} 1 = 1 & n = 0 \\ 5a_1 + 1 = 0 \implies a_1 = -\frac{1}{5} & n = 1 \\ 5a_2 + 10a_1^2 + a_1 = 0 \implies a_2 = -\frac{1}{25} & n = 2 \\ 5a_3 + 20a_1a_2 + 10a_1^3 + a_2 = 0 \implies a_3 = -\frac{1}{125} & n = 3 \end{cases}$$

We also find $a_4 = 0$ for some reason. So the pattern doesn't fit This means:

$$a(\epsilon) = 1 - \frac{1}{5}\epsilon - \frac{1}{25}\epsilon^2 - \frac{1}{125}\epsilon^3 + \dots$$

$$a(1) \approx 0.752 \quad a_{\text{numerical}} = 0.7549\dots$$

We find that the solution actually moves away from the actual solution on the 8th and 9th terms

We require the value of epsilon to be quite small such to converge to relatively accurate answers.

We tried to convert the hard problem into several smaller easy(ish) problems. We will extend this to DEs and real-world applications soon.

0.2.2 Notation

\sim (asymptotic) and \ll (negligible)

Say we have $f(x)$ and $g(x)$ then:

$$f(x) \sim g(x), \quad x \rightarrow x_0$$

This means that $f(x)$ is asymptotic to $g(x)$, and approaches it as x goes to x_0 . This statement is equivalent to saying:

$$\lim_{x \rightarrow x_0} \frac{f(x)}{g(x)} = 1$$

There are two parts to this notation: the expression with the \sim and the associated limit ($x \rightarrow x_0$). Strictly speaking, both of these are necessary for this to make sense.

Example:

$$\sin(x) \sim x, \quad x \rightarrow 0$$

Which is equivalent to

$$\lim_{x \rightarrow 0} \frac{\sin(x)}{x} = \lim_{x \rightarrow 0} \frac{\cos(x)}{1} = 1$$

This is a way to check for asymptotic relationships.

More examples:

$$e^x \sim 1, \quad x \rightarrow 0$$

$$\frac{1}{\epsilon} \sim \frac{1}{\epsilon} + 1, \quad \epsilon \rightarrow 0$$

$$\epsilon^2 \sim \epsilon^2 + \epsilon^3, \quad \epsilon \rightarrow 0$$

$$x^{1/3} \sim 2, \quad x \rightarrow 8$$

$$e^x \sim e^x + 2, \quad x \rightarrow \infty$$

Of course for many of these you could use equality

Similarly there is non-asymptotic statements:

$$\epsilon^2 \not\sim \epsilon, \quad \epsilon \rightarrow 0$$

$$\sin(x) \not\sim x^2, \quad x \rightarrow 0$$

Cannot say things like:

$$x^2 \sim 0, \quad x \rightarrow 0$$

That would be very dumb

Other notation

$$f(x) \ll g(x), \quad x \rightarrow x_0$$

Means that

$$\lim_{x \rightarrow 0} \frac{f(x)}{g(x)} = 0$$

I.e. it means $f(x)$ becomes much smaller than $g(x)$ as $x \rightarrow x_0$.

Examples:

$$\epsilon \ll \frac{1}{\epsilon}, \quad \epsilon \rightarrow 0$$

$$\lim_{\epsilon \rightarrow 0} \frac{\epsilon}{\frac{1}{\epsilon}} = \lim_{\epsilon \rightarrow 0} \epsilon^2 = 0$$

$$\frac{1}{x} \ll x, \quad x \rightarrow \infty$$

$$\sqrt{x} \ll \sqrt[3]{x}, \quad x \rightarrow 0^+$$

Slightly less trivial example:

$$\log(x)^5 \ll x^{1/4}, \quad x \rightarrow \infty$$

$$x \ll -10, \quad x \rightarrow 0^+$$

$$\lim_{x \rightarrow 0^+} \frac{x}{-10} = 0$$

So some counterintuitive cases work...

$$af(x) \ll bg(x), \quad x \rightarrow x_0$$

$$\text{if } f(x) \ll g(x), x \rightarrow x_0$$

$$\text{since } \lim_{x \rightarrow x_0} \frac{af(x)}{bg(x)} = \frac{a}{b} \lim_{x \rightarrow x_0} \frac{f(x)}{g(x)} = 0$$

Asymptotic relations work like equations, normal arithmetic ($+$, $-$, $/$, \times , $\frac{\partial}{\partial}$, \int) work but sometimes it may not be valid. For example it may not be valid to exponentiate both sides

Switching between asymptotic and exact relations:

Say we have 3 functions $f(x)$, $g(x)$ and $h(x)$

$$f(x) = g(x) + h(x)$$

With

$$h(x) \ll g(x), \quad x \rightarrow x_0$$

Then we have

$$f(x) \sim g(x), \quad x \rightarrow x_0$$

We could go the other way, starting with:

$$f(x) \sim g(x), \quad x \rightarrow x_0$$

Then:

$$f(x) = g(x) + h(x), \quad \text{with } h(x) \ll g(x), \quad x \rightarrow x_0$$

More examples:

$$e^x \sim 1, \quad x \rightarrow 0$$

$$e^x = 1 + h(x), \quad h(x) \ll 1, \quad x \rightarrow 0$$

Unfortunately we can't infer much about $h(x)$ from this.

If we consider the quintic again, but put the epsilon over the x^5 instead of the x .

$$\epsilon x^5 + x = 1$$

This is an example of a **singular perturbation** problem, since the behaviour of this equation is fundamentally different in the limit $\epsilon \rightarrow 0$.

Method of dominant balance

A systematic way to analyse the behaviour of the equation in the limit $\epsilon \rightarrow 0$ and converting the equation into a simpler asymptotic relation. Method: The three possibilities for $\epsilon x^5 + x = 1$ are

1. $x \sim 1$ as $\epsilon \rightarrow 0$ (neglect ϵx^5)

This is saying $\epsilon x^5 \ll x$ and $\epsilon x^5 \ll 1$ as $\epsilon \rightarrow 0$ Starting with the first, this is equivalent to

$$\epsilon x^4 \ll 1, \quad \epsilon \rightarrow 0$$

Since $x \sim 1$:

$$\epsilon \ll 1, \epsilon \rightarrow 0$$

By the same token the second term is good.

So this first set looks good (i.e. one root near $x = 1$).

2. $\epsilon x^5 \sim 1$ as $\epsilon \rightarrow 0$ (neglect x)

Saying $x \ll \epsilon x^5$ and $x \ll 1$ as $\epsilon \rightarrow 0$. Starting with the asymptotic equation:

$$\begin{aligned} \epsilon x^5 &\sim 1, \quad \epsilon \rightarrow 0 \\ x^5 &\sim \frac{1}{\epsilon}, \quad \epsilon \rightarrow 0 \\ x &\sim \frac{\omega}{\epsilon^{1/5}}, \quad \epsilon \rightarrow 0 \end{aligned}$$

Where $\omega^5 = 1$

Note that the RHS gets infinitely large very quickly as $\epsilon \rightarrow 0$, which is a contradiction since we have assumed $x \ll 1$, as $\epsilon \rightarrow 0$.

This logical inconsistency means this is not a valid balance.

3. $\epsilon x^5 \sim -x$ as $\epsilon \rightarrow 0$ (neglect 1)

We are saying $1 \ll \epsilon x^5$ and $1 \ll x$ (we can drop the minus as it is a constant) as $\epsilon \rightarrow 0$

Look at the initial expression

$$\begin{aligned} \epsilon x^5 &\sim -x, \quad \epsilon \rightarrow 0 \\ x^4 &\sim -\frac{1}{\epsilon}, \quad \epsilon \rightarrow 0 \\ x &\sim \frac{\omega}{\epsilon^{1/4}}, \quad \epsilon \rightarrow 0 \end{aligned}$$

Where $\omega^4 = -1$. RHS blows up as $\epsilon \rightarrow 0$, but this is okay since we have said $1 \ll -x$! I.e. 1 is negligible compared to x as $\epsilon \rightarrow 0$. For $1 \ll \epsilon x^5$, $\epsilon \rightarrow 0$

$$\begin{aligned} x &\sim \frac{\omega}{\epsilon^{1/4}}, \quad \epsilon \rightarrow 0 \\ x^5 &\sim \frac{\omega^5}{\epsilon^{5/4}}, \quad \epsilon \rightarrow 0 \\ \epsilon x^5 &\sim \frac{\omega^5}{\epsilon^{1/4}}, \quad \epsilon \rightarrow 0 \end{aligned}$$

The RHS blows up (again) which satisfies what we want. We actually find that the *RHS* has 4 roots, which makes up for the other 4 roots to the quintic

Consider a linear second-order homogeneous de in standard form:

$$y'' + a(x)y' + b(x)y = 0$$

Say we want to know about the **local behaviour** around $x = x_0$, and construct an approximate solution. This depends on the behaviour of $a(x)$ and $b(x)$ near $x = x_0$

1. $x = x_0$ is an ordinary point: use a Taylor series expansion

$$y = \sum_{n=0}^{\infty} a_n (x - x_0)^n$$

2. $x = x_0$ is a regular singular point: use a Frobenius expansion

$$y = (x - x_0)^\alpha \sum_{n=0}^{\infty} a_n$$

3. $x = x_0$ is an irregular singular point: use asymptotics. Start by assuming

$$y(x) = e^{S(x)}$$

And then construct a solution by repeatedly using the method of dominant balance.

Example:

$$\frac{dy}{dx} - \frac{1}{2}y = 0$$

Use the $x = 1/t$ transformation:

$$\frac{dy}{dt} + \frac{y}{2t^2} = 0$$

All points of the equation are ordinary, except $t = 0$ ($x \rightarrow \infty$) which is an irregular singular point

$$\frac{dy}{dx} - \frac{1}{2x}y = 0$$

This has a regular singular point at $x = 0$. What happens at $x = \infty$.

$$\frac{dy}{dx} - \frac{1}{2x^2}y = 0$$

This has an irregular singular point at $x = 0$. What happens at $x = \infty$?

Example: The DE:

$$x^3 y'' = y$$

Lets look at the local behaviour as $x \rightarrow 0$. Solve with the method of dominant balance
Rearrange as

$$y'' = \frac{1}{x^3}y$$

Irregular single point at $x = 0$. I.e. $x^2 \frac{1}{x^3} = \frac{1}{x}$... not analytic at $x = 0$.

Try forming solution of the form

$$\begin{aligned} y &= e^{S(x)} \\ y' &= S' e^{S(x)} \\ y'' &= S'' e^S + (S')^2 e^S \\ &= (S'' + (S')^2) e^S \end{aligned}$$

Where $S = S(x)$.

Equation becomes:

$$S'' + (S')^2 = \frac{1}{x^3}$$

Now use the method of dominant balance.

1. Neglect $(S')^2$:

$S'' \sim \frac{1}{x^3}$, $x \rightarrow 0$. Integrate once:

$$S' \sim \frac{-1}{2x^2} \implies (S')^2 \sim \frac{1}{4x^4}, \quad x \rightarrow 0$$

But we have assumed $(S')^2 \ll \frac{1}{x^3}$, $x \rightarrow 0$. Contradiction since $\frac{1}{4x^4}$ grows faster than $\frac{1}{x^3}$ as $x \rightarrow 0$.

2. Neglect S'' :

$(S')^2 \sim \frac{1}{x^3}$, $x \rightarrow 0$.

$$\begin{aligned} S' &\sim \pm x^{-3/2}, \quad x \rightarrow 0 \\ \implies S'' &\sim \mp \frac{3}{2} x^{-5/2} \ll x^{-3}, \quad x \rightarrow 0 \end{aligned}$$

So the assumption is valid.

3. Neglect $\frac{1}{x^3}$:

$S'' \sim -(S')^2$, $x \rightarrow 0$

Let $T = S'$. Then the equation is $T' \sim -T^2$ as $x \rightarrow 0$. Rearranging then integrating gives:

$$\begin{aligned} -\frac{1}{T^2} T' &\sim 1 \\ T^{-1} &\sim x + a \sim a, \quad x \rightarrow 0 \\ (S')^2 &\sim \frac{1}{a^2} \ll \frac{1}{x^3}, \quad x \rightarrow 0 \end{aligned}$$

Which is a contradiction since we assumed that $\frac{1}{x^3}$ was negligible.

So the valid balance is

$$\begin{aligned} (S')^2 &\sim \frac{1}{x^3}, \quad x \rightarrow 0 \\ \implies S' &\sim \pm x^{-3/2}, \quad x \rightarrow 0 \\ S &\sim \mp 2x^{-1/2}, \quad x \rightarrow 0 \end{aligned}$$

(we don't need the constant of integration since it will be negligible as $x \rightarrow 0$).

We can convert this to an exact relation:

$$S = \mp 2x^{-1/2} + C(x)$$

Where $C(x) \ll x^{-1/2}$, $x \rightarrow 0$.

Now put this back into the S DE

$$\begin{aligned}
S'' + (S')^2 &= \frac{1}{x^3} \\
\mp \frac{3}{2}x^{-5/2} + C''(x) + (\pm x^{-3/2} + C'(x))^2 &= x^{-3} \\
\mp \frac{3}{2}x^{-5/2} + C''(x) + x^{-3} \pm 2C'(x)x^{-3/2} + C'(x)^2 &= x^{-3} \\
\mp \frac{3}{2}x^{-5/2} + C''(x) \pm 2C'(x)x^{-3/2} + C'(x)^2 &= 0
\end{aligned}$$

Use some dominant balance again. But fortunately we already know $C \ll x^{-1/2}$ as $x \rightarrow 0$. Which means $C' \ll x^{-3/2}$ as $x \rightarrow 0$ (can drop the constant) and $C'' \ll x^{-5/2}$, as $x \rightarrow 0$. This last statement simplifies our equation and it becomes

$$\mp \frac{3}{2}x^{-5/2} \pm 2C'(x)x^{-3/2} + C'(x)^2 = 0$$

We also get (using the $C' \ll x^{-3/2}$) gives

$$(C')^2 \ll C'x^{-3/2}$$

Meaning that we can drop the $(C')^2$ term. Giving

$$\mp \frac{3}{2}x^{-5/2} \pm 2C'(x)x^{-3/2} = 0$$

Solve C now:

$$\begin{aligned}
2C'x^{-3/2} &\sim \frac{3}{2}x^{-5/2}, \quad x \rightarrow 0 \\
C' &\sim \frac{3}{4}x^{-1} \rightarrow 0 \\
C &\sim \frac{3}{4}\log(x), \quad x \rightarrow 0
\end{aligned}$$

Again neglecting the constant of integration for the same reason as before

$$S \sim \mp 2x^{-1/2} + \frac{3}{4}\log(x), \quad x \rightarrow 0$$

But if we want to be exact again we would have to say

$$C = \frac{3}{4}\log x + D(x)$$

Where $D(x) \ll \log(x)$. Gives:

$$\begin{aligned}
C' &= \frac{3}{4}\frac{1}{x} + D' \\
C'' &= -\frac{3}{4}x^{-2} + D''
\end{aligned}$$

Plugging this into the exact C equation:

$$\mp \frac{3}{2}x^{-5/2} - \frac{3}{4}x^{-2} + D'' \pm 2x^{-3/2}\left(\frac{3}{4}\frac{1}{x} + D'\right) + \left(\frac{3}{4}\frac{1}{x} + D'\right)^2 = 0$$

$$\mp -\frac{3}{4}x^{-2} + D'' \pm 2x^{-3/2}D' + \left(\frac{3}{4}x^{-1} + D'\right)^2 = 0$$

You end up with:

$$0 = -\frac{3}{4}x^{-2} + D'' \pm 2D'x^{-3/2} + (D')^2 + \frac{9}{16}x^{-2} + \frac{3}{2}x^{-1}D'$$

$$0 = -\frac{3}{16}x^{-2} + D'' + (\pm 2x^{-3/2} + \frac{3}{2}x^{-1})D' + (D')^2$$

Can immediately neglect the $\frac{3}{2}x^{-1}D'$ term since $x^{-1} \ll x^{-3/2}$ as $x \rightarrow 0$ (this is easy to spot since they're both just x terms) We know the following about D :

$$\begin{aligned} D &\ll \log x \\ D' &\ll x^{-1} \\ D'' &\ll -x^{-2} \end{aligned}$$

As $x \rightarrow 0$.

The last of these means we can neglect the D'' term since theres an x^{-2} term.

$$0 \sim -\frac{3}{16}x^{-2} + (\pm 2x^{-3/2} + \frac{3}{2}x^{-1})D' + (D')^2$$

Multiplying the second line by D' gives $(D')^2 \ll x^{-1}D'$. And since we have already neglected the $x^{-1}D'$ term, we can neglect the $(D')^2$ term The remaining balance is then

$$2x^{-3/2}D' \sim \pm \frac{3}{16}x^{-2}$$

$$D' \sim \pm \frac{3}{32}x^{-1/2}, \quad x \rightarrow 0$$

We need to integrate this BUT WE HAVE TO KEEP THE CONSTANT OF INTEGRATION. Since the right hand side vanishes as $x \rightarrow 0$ i.e. $x^{1/2} \ll 1$.

$$D(x) - d \sim \pm \frac{3}{16}x^{1/2}$$

Where d is the constant of integration. So now we have

$$D(x) = d + \delta(x)$$

Where $\delta(x) \sim \pm \frac{3}{16}x^{1/2}$

So we could keep going but lets just consider

$$S(x) \sim \mp 2x^{-1/2} + \frac{3}{4} \log x + d$$

Exponentiating both sides gives

$$\begin{aligned} y(x) &\sim \exp\left(\mp 2x^{-1/2} + \frac{3}{4} \log x + d\right) \\ &\sim c_1 x^{3/4} e^{2x^{-1/2}} = c_1 x^{3/4} e^{2x^{-1/2}} + c_2 x^{3/4} e^{-2x^{-1/2}} \end{aligned}$$

Where $c_1 = e^d$

We can actually drop the c_2 term since that will get very small

By plotting this and dividing it through gives a constant of about 0.15 Why could we exponentiate this???

Procedure summary:

1. Assume a solution of form

$$y = e^{S(x)}$$

Approximate $S(x)$ by:

2. Drop all negligible terms as $x \rightarrow 0$ (or whatever)
3. Solve the simpler asymptotic relation (verify assumptions about negligible terms)
4. Replace the asymptotic relation with an equation by introducing an arbitrary function which is \ll than what we already found.
5. Repeat
6. When a 'controlling factor' is found - enough terms in the approximation to $S(x)$ that when we put them back into $y = e^{S(x)}$, adding additional terms will make no difference

$$2x^{-1/2} \sim 2x^{-1/2} + \frac{3}{4} \log x, \quad x \rightarrow 0$$

$$e^{2x^{-1/2}} \sim e^{2x^{-1/2}} x^{3/4}$$

That second line is absolutely garbage.

$$\lim_{x \rightarrow 0} \frac{e^{2x^{-1/2}} x^{3/4}}{e^{2x^{-1/2}}} = \lim_{x \rightarrow 0}$$

In general if you have

$$f(x) \sim g(x), \quad x \rightarrow x_0$$

And want to exponentiate:

$$e^{f(x)} \sim e^{g(x)}, \quad x \rightarrow x_0$$

This is only valid if:

$$f(x) - g(x) \ll 1, \quad x \rightarrow x_0$$

Example: solve the airy equation as $x \rightarrow \infty$ using the method of dominant balance

$$y'' = xy$$

Check $x \rightarrow \infty$ is an irregular singular point. Lets sub $x = 1/t$ to get

$$\frac{d^2 y}{dt^2} + \frac{2}{t} \frac{dy}{dt} = \frac{1}{t^5} y$$

The y term is divided by t^5 and $5 > t$ so $t = 0$ is an irregular singular point (so $x \rightarrow \infty$ is too)
Make the substitution $y = e^{S(x)}$

$$S'' + (S')^2 = x$$

Now use dominant balance:

1. $S'' \sim x$, neglect $(S')^2$ Integration gives $S' \sim \frac{1}{2}x^2$ which implies $(S')^2 \sim \frac{1}{4}x^4$ as $x \rightarrow \infty$. But we assumed $(S')^2 \ll x$ so this is a contradiction
2. $(S')^2 \sim x$ and neglect S'' Square root and differentiate gives $S'' \sim \pm \frac{1}{2}x^{-1/2}$ and $x^{-1/2} \ll x$ as $x \rightarrow \infty$ so this is valid.

3. $S'' \sim -(S')^2$ neglecting x Integration gives $S' \sim 1/(x+1) \sim 1/x$ but we assumed $x \ll (S')^2$ so this is a contradiction

So we use 2. We then get the distinguished limit as:

$$(S')^2 \sim x \implies S \sim \pm \frac{2}{3}x^{3/2}, \quad x \rightarrow \infty$$

Proceeding (and just taking the positive bit) we get

$$S(x) = \frac{2}{3}x^{3/2} + C(x)$$

Where $C(x) \ll x^{3/2}$ as $x \rightarrow \infty$ Sub back into the DE for S to get

$$S'' + (S')^2 = x$$

$$\frac{1}{2}x^{-1/2} + C'' + (x^{1/2} + C')^2 = x$$

$$\frac{1}{2}x^{-1/2} + C'' + 2C'x^{1/2} + (C')^2 = 0$$

$$\frac{1}{2}x^{-1/2} + C'' + C'(2x^{1/2} + C') = 0$$

Now convert to an asymptotic relation: C and its derivatives:

$$C(x) \ll x^{3/2}$$

$$C'(x) \ll x^{1/2}$$

$$C''(x) \ll x^{-1/2}$$

So we can immediately drop the C'' term since there is a $x^{-1/2}$ term. We can drop the C' term in the brackets, giving

$$2C'x^{1/2} \sim -\frac{1}{2}x^{-1/2}, \quad x \rightarrow \infty$$

$$C' \sim -\frac{1}{4}x^{-1} \implies C \sim -\frac{1}{4}\log x$$

as $x \rightarrow \infty$.

Meaning

$$C(x) = -\frac{1}{4}\log x + D(x), \quad D(x) \ll \log x$$

as $x \rightarrow \infty$

Sub this into C 's equation (before it became asymptotic):

$$\frac{1}{2}x^{-1/2} + \frac{1}{4}x^{-2} + D'' + 2x^{1/2}\left(-\frac{1}{4}x^{-1} + D'\right) + \left(-\frac{1}{4}x^{-1} + D'\right)^2 = 0$$

Which simplifies to

$$\frac{5}{16}x^{-2} + D'' + D'(2x^{1/2} - \frac{1}{2}x^{-1}) + (D')^2 = 0$$

Now make it asymptotic:

$$D \ll \log x$$

$$D' \ll x^{-1}$$

$$D'' \ll x^{-2}$$

As $x \rightarrow \infty$ So we can neglect D'' and $(D')^2$ since we have already neglected $x^{-1}D'$. We also have in the brackets 2 powers of x , so we drop the smaller ($\frac{1}{2}x^{-1}$)

$$2D'x^{1/2} \sim -\frac{5}{16}x^{-2} \implies D' \sim -\frac{5}{32}x^{-5/2}$$

$$D \sim d + \frac{5}{48}x^{-3/2} \sim d$$

As $x \rightarrow \infty$. We have to drop the $x^{-3/2}$ since it becomes negligible compared to a constant
Now since we ended up with a constant we dump it into our S equation:

$$\begin{aligned} S &\sim \frac{2}{3}x^{3/2} - \frac{1}{4}\log x + d \quad x \rightarrow \infty \\ \implies y = e^S &\sim c_1 e^{2/3x^{3/2}} x^{-1/4}, \quad x \rightarrow \infty \end{aligned}$$

Where $c_1 = e^d$ We can see clearly that the other solution is

$$y = c_2 e^{-2/3x^{3/2}} x^{-1/4}$$

From where we dropped the sign.

The Airy function approximations are defined as:

$$\begin{aligned} Ai(x) &\sim \frac{1}{2\sqrt{\pi}} e^{-2/3x^{3/2}} x^{-1/4} \\ Bi(x) &\sim \frac{1}{\sqrt{\pi}} e^{2/3x^{3/2}} x^{-1/4} \end{aligned}$$

This makes us want to talk about: sub-dominance and behaviour of asymptotic relations in the complex plane.

Sub-dominance is basically saying that one of the linearly independent solutions might dominate and have a greater effect than the other.

Example:

$$\sinh(x) := \frac{1}{2}(e^x - e^{-x})$$

For $x \rightarrow \infty$

$$\sinh(x) \sim \frac{1}{2}e^x, \quad x \rightarrow \infty$$

Here e^x dominates e^{-x} so we will say $-\frac{1}{2}e^{-x}$ is subdominant.

If we instead go $x \rightarrow -\infty$

$$\sinh(x) \sim -\frac{1}{2}e^{-x}, \quad x \rightarrow -\infty$$

So $\frac{1}{2}e^x$ is subdominant

If we consider the Airy equation $y'' = xy$ and enforced a boundary condition.

$$y = c_1 Ai(x) + c_2 Bi(x)$$

Subject to

$$\lim_{x \rightarrow \infty} y(x) := y(\infty) = 0$$

Then we find c_2 comes out as 0, since $Bi(x)$ blows up towards infinity

But we have just been assuming x is real. What if we start considering z (complex numbers)?

$$\sinh(z) = \frac{1}{2}(e^z - e^{-z})$$

In the complex z we now have to consider \arg and magnitude. (if we take $\arg(z) = 0$ then we get the previous problem to $+\infty$ and $\arg(z) = \pi$ then we get the $-\infty$ case) So we would write this as

$$\sinh(z) \sim \frac{1}{2}e^z, \quad z \rightarrow \infty, \quad -\pi/2 < \arg(z) < \pi/2$$

$$\sinh(z) \sim -\frac{1}{2}e^{-z}, \quad z \rightarrow -\infty, \quad \pi/2 < \arg(z) < 3\pi/2$$

This behaviour we call Stoke's phenomenon (where the change of behaviour changing in different regions of the complex plane)

Note we only have strict inequalities. When we have

$$\arg(z) = \pi/2, 3\pi/2$$

Then we get $e^z = e^{x+iy} = e^{iy}$. So we have purely oscillatory behaviour. These lines (we will call) Stoke's lines. The regions where there is no oscillatory behaviour (in this case $\arg(z) = 0, \pi$) we call anti-Stokes lines. These names will sometimes swap based on literature. Really useful.

Big O and small o notation.

- $\mathcal{O}(x)$: A function of order of the argument x and HIGHER.
- $o(x)$: we stopped when we reached order x .

E.g. Taylor series for \cos

$$\cos(x) = 1 - \frac{x^2}{2!} + \frac{x^4}{4!} + \dots$$

Then we can write

$$\cos(x) = 1 - \frac{x^2}{2!} + \mathcal{O}(x^4)$$

Or

$$\cos(x) = 1 - \frac{x^2}{2!} + o(x^2)$$

We actually define \mathcal{O} such that:

$$f(x) = \mathcal{O}(G(x)), \quad x \rightarrow x_0$$

$$\lim_{x \rightarrow x_0} \frac{f(x)}{g(x)} = A$$

Or alternatively write

$$|f(x)| \leq A|g(x)|$$

For some constant A .

We won't really use o but its useful to know.

$$f(x) = o(g(x)), \quad x \rightarrow x_0$$

If $f(x) \ll g(x)$

If we have

$$x \sim \delta_0 x_0 + \delta_1 x_1 + \delta_2 x_2$$

$$x = \delta_0 x_0 + \delta_1 x_1 + \mathcal{O}(\delta_2)$$

Or as an example of little o

$$x = \delta_0 x_0 + \delta_1 x_1 + o(\delta_1)$$

0.3 Sequences and Series

Recall that a series

$$\sum_{n=0}^{\infty} f_n(z)$$

Converges at some fixed value of z if for an arbitrary $\epsilon > 0$ it is possible to find a number $N_0(z, \epsilon)$ such that

$$\left| \sum_{n=M}^N f_n(z) \right| < \epsilon, \text{ for all } M, N > N_0$$

The series converges to a function $f(z)$ at some fixed value of z if for an arbitrary $\epsilon > 0$ it is possible to find a number $N_0(z, \epsilon)$ such that

$$\left| f(z) - \sum_{n=M}^N f_n(z) \right| < \epsilon, \text{ for all } M, N > N_0$$

Equivalently we can think of series converging as its terms decaying sufficiently quickly as $N \rightarrow \infty$

Consider the error function, defined as

$$\operatorname{erf}(z) := \frac{2}{\sqrt{\pi}} \int_0^z e^{-t^2} dt$$

Lets get a series representation (lets expand that exponential) I.e. use

$$e^{-t^2} = \sum_0^{\infty} \frac{(-t^2)^n}{n!}$$

$$\begin{aligned} \operatorname{erf}(z) &= \frac{2}{\sqrt{\pi}} \int_0^z e^{-t^2} dt \\ &= \frac{2}{\sqrt{\pi}} \int_0^z \sum_0^{\infty} \frac{(-t^2)^n}{n!} dt \\ &= \frac{2}{\sqrt{\pi}} \sum_0^{\infty} \int_0^z \frac{(-t^2)^n}{n!} dt \\ &= \frac{2}{\sqrt{\pi}} \sum_{n=0}^{\infty} \frac{(-1)^n z^{2n+1}}{(2n+1)n!} \\ &= \frac{2}{\sqrt{\pi}} z \left(-\frac{z^3}{3} + \frac{z^5}{10} - \frac{z^7}{42} + \frac{z^9}{216} - \dots \right) \end{aligned}$$

Which is convergent (can show this using radius of convergence). But is it useful?

Alternatively

$$\begin{aligned} \operatorname{erf}(z) &= \frac{2}{\sqrt{\pi}} \int_0^z e^{-t^2} dt \\ &= \frac{2}{\sqrt{\pi}} \left(\int_0^{\infty} e^{-t^2} dt - \int_z^{\infty} e^{-t^2} dt \right) \\ &= \frac{2}{\sqrt{\pi}} \int_0^{\infty} e^{-t^2} dt - \frac{2}{\sqrt{\pi}} \int_z^{\infty} e^{-t^2} dt \\ &= 1 - \frac{2}{\sqrt{\pi}} \int_z^{\infty} e^{-t^2} dt \end{aligned}$$

Integration by parts:

$$\begin{aligned}
 \int_z^\infty e^{-t^2} dt &= \int_z^\infty \frac{e^{-t^2}}{2t} dt \\
 &= \frac{e^{-z^2}}{2z} - \int_z^\infty \frac{e^{-t^2}}{2t^2} dt \\
 &= \frac{e^{-z^2}}{2z} - \int_z^\infty \frac{2te^{-t^2}}{4t^3} dt \\
 &= \frac{e^{-z^2}}{2z} - \frac{e^{-z^2}}{4z^3} - \int_z^\infty \frac{e^{-t^2}}{12t^2} dt \\
 \operatorname{erf}(z) &= 1 - \frac{1}{z\sqrt{\pi}} e^{-z^2} \left(1 - \frac{1}{2z^2} + \frac{1*3}{(2z^2)^2} - \frac{1*3*5}{(2z^2)^3} \right)
 \end{aligned}$$

Even though this is a divergent series, it converges for small values of n (so if we only take say the first like 3 terms). This makes it an asymptotic sequence.

Introduces a concept called ‘optimal truncation’

A sequence $\{f_n(\epsilon)\}$ is an asymptotic sequence as $\epsilon \rightarrow 0$ if

$$f_{n+1}(\epsilon) \ll f_n(\epsilon), \quad \epsilon \rightarrow 0$$

For all n .

Some examples:

$$\begin{aligned}
 \epsilon^{-1}, 1, \epsilon, \epsilon^2, \dots, \quad \epsilon \rightarrow 0 \\
 1, \frac{1}{x}, \frac{1}{x^2}, \dots, \quad x \rightarrow \infty
 \end{aligned}$$

If we have a function $f(\epsilon)$, a series $\sum_{n=0}^\infty f_n(\epsilon)$ is an asymptotic expansion (or approximation) to this function if

$$f(\epsilon) - \sum_{n=0}^N f_n(\epsilon) \ll f_N(\epsilon)$$

I.e. the remainder between the approximation and the function is smaller than the last included term. This can be written as

$$f(\epsilon) \sim \sum_{n=0}^\infty f_n(\epsilon), \quad \epsilon \rightarrow 0$$

The main example of this is an asymptotic power series in ϵ

$$f(\epsilon) \sim \sum_{n=0}^\infty a_n \epsilon^n, \quad \epsilon \rightarrow 0$$

The power of ϵ in that sum can kinda be anything though.

Asymptotic approximations are interesting since you can have many correct asymptotic approximations. E.g. $\tan(\epsilon)$, $\epsilon \rightarrow 0$

$$\begin{aligned}
 \tan(\epsilon) &\sim \epsilon + \frac{\epsilon^3}{3} + \frac{2\epsilon^5}{15} + \dots \\
 &\sim \sin \epsilon + \frac{1}{2}(\sin \epsilon)^3 + \frac{3}{8}(\sin \epsilon)^5 + \dots
 \end{aligned}$$

The course is pretty much going to be about developing expansions in the form $f(x; \epsilon)$, i.e. involving an independent variable x and a parameter ϵ .

The most general form is

$$f(x; \epsilon) \sim \sum_{n=0}^{\infty} a_n(x) \delta_n(\epsilon), \quad \epsilon \rightarrow 0$$

We usually take $\delta_n(\epsilon) = \epsilon^n$.

We only want to take a few terms to get an accurate answer - too many terms will start to diverge.

Optimal truncation, a.k.a superasymptotic representation - terminating the series before the series starts to diverge. The usual method is to look for an increase in magnitude and then terminate that term and all following terms.

Some numerical methods can improve the convergence of divergent series to the 'right' answer (in certain circumstances). This might involve alternative ways of summing the terms in a series - adding the terms is nearly the most inefficient method. E.g. Shanks transformation and Padé summation

0.4 Perturbation Methods

This section looks at global behaviour rather than local solutions (what the last section looked at). We will look at boundary-layer problems, where the solution might be significantly different in a thin region compared to the rest of the domain.

In most terms a perturbation is a small kick via a small parameter ϵ . These parameters can be introduced into modelling problems in a variety of ways. E.g.

- Initial conditions: a usually stable physical situation can be given a small 'kick' and look at the response
- Boundary conditions, a perturbation can be introduced at a boundary (inhomogeneity or shape to the boundary)
- Variable scaling - different characteristic length scales in different directions - rescaling is necessary
- Parameter scaling - assumptions around dominant physical processes to simplify analysis. e.g. changing Reynolds number!

There are other situations when you might introduce perturbations as well.

We have already been essentially using some perturbation methods. There are 2 types of problems

- Regular perturbation problems: the structure of the problem is unchanged in the limit $\epsilon \rightarrow 0$

$$x^5 + \epsilon x = 1$$

$$y'' + 2\epsilon y = 1$$

- Singular perturbation problems: The solution behaves differently in the limit $\epsilon \rightarrow 0$. Usually the highest power/derivative is what is multiplied by ϵ these one may change the number of solutions. These are common in Boundary-layer problems.

$$\epsilon x^5 + x = 1$$

$$\epsilon y'' + 2y = 1$$

In general we will seek solutions of form

$$y(x) = \sum_{n=0}^{\infty} \epsilon^n y_n(x) = y_0(x) + \epsilon y_1(x) + \epsilon^2 y_2(x) + \mathcal{O}(\epsilon^2)$$

This is typically iterative. We find the leading order solution $y_0(x)$ and then solve for $y_1(x)$ (which usually depends on y_0). Then repeat to continually get the next correcting terms (until you get sick of it basically). Usually we only care about the leading order term, or sometimes the first-order correction.

0.4.1 ODEs

Lets try solve some ODE examples!

Projectile motion:

$$\frac{d^2x}{dt^2} = -\frac{1}{(1 + \epsilon x)^2}, \quad x(0) = 1, \quad x'(0) = \alpha$$

Where $\epsilon \rightarrow 0$ is the ratio of the length scale of interest to that of the radius of the Earth. So this is valid so long as the projectile doesn't go ludicrously high.

So assume $x(t) = x_0(t) + \epsilon x_1(t) + \epsilon^2 x_2(t) + \mathcal{O}(\epsilon^3)$. And sub it in:

$$x'' = x_0'' + \epsilon x_1'' + \epsilon^2 x_2'' + \mathcal{O}(\epsilon^3)$$

Note the right hand side is a binomial expansion with a negative power rather than positive.

$$-\frac{1}{(1 + \epsilon x)^2} = \sum_{k=0}^{\infty} \binom{-2}{k} (\epsilon x)^k = -1 + 2\epsilon x - 3\epsilon^2 x^2 + \mathcal{O}(\epsilon^3)$$

Now using the series form for x :

$$RHS = -1 + 2\epsilon(x_0 + \epsilon x_1 + \mathcal{O}(\epsilon^2)) - 3\epsilon^2(x_0 + \epsilon x_1 + \mathcal{O}(\epsilon^2))^2 + \mathcal{O}(\epsilon^3)$$

Now we collect like powers of epsilon

$$RHS = -1 + \epsilon(2x_0) + \epsilon^2(2x_1 - 3x_0^2) + \mathcal{O}(\epsilon^3)$$

Now we must make sure the ICs/BCs are satisfied:

$$x(0) = x_0(0) + \epsilon x_1(0) + \epsilon^2 x_2(0) + \mathcal{O}(\epsilon^3) = 1$$

$$x'(0) = x_0'(0) + \epsilon x_1'(0) + \epsilon^2 x_2'(0) + \mathcal{O}(\epsilon^3) = \alpha$$

So now we want the $LHS = RHS$ and we do this by equating like terms (powers of ϵ).

$$\begin{aligned} x_0'' &= -1, & x_0(0) &= 1, & x_0'(0) &= \alpha \\ x_1'' &= 2x_0 & x_1(0) &= 0, & x_1'(0) &= 0 \\ x_2'' &= 2x_1 - 3x_0^2 & x_2(0) &= 0, & x_2'(0) &= 0 \\ &\vdots & & & & \end{aligned}$$

Now using the ICs, start solving x_0 .

$$\begin{aligned}
x_0'' &= -1 \\
x_0' &= -t + c, \quad x(0)' = \alpha x_0' = -t + \alpha \\
x_0 &= \frac{-t^2}{2} + \alpha t + c_2, \quad x(0) = 1 \\
\implies x_0 &= -\frac{1}{2}t^2 + \alpha t + 1
\end{aligned}$$

Now x_1 (and we repeat for the other ones) Note we can ignore constants in this case since they are all 0.

$$\begin{aligned}
x_1'' &= 2x_0 = -t^2 + 2\alpha t + 2 \\
\implies x_1' &= -\frac{1}{3}t^3 + \alpha t^2 + 2t \\
x_1 &= -\frac{1}{12}t^4 + \frac{1}{3}\alpha t^3 + t^2
\end{aligned}$$

Since this is still an asymptotic series, the solution will only be valid if

$$\epsilon(-\frac{1}{2}t^4 + \frac{\alpha}{3}t^3 + t^2) \ll -\frac{1}{2}t^2 + \alpha t + 1, \quad \epsilon \rightarrow 0$$

So this assumption may not hold when t gets quite large, since the left hand side has higher order powers of t .

So it will hold well given:

$$x_k \epsilon^k \ll x_{k-1} \epsilon^{k-1} \ll \dots \ll x_1 \epsilon \ll x_0$$

So when ϵ and t get reasonably big, this assumption breaks for us. I.e. we want

$$\epsilon t^4 \ll t^2$$

Or rearrange for $t \ll \frac{1}{\sqrt{\epsilon}}$ So we lose validity when (in order notation) $t = \mathcal{O}(\epsilon^{-1/2})$

Another example: shape of a diving board (depression of it) The diving board protrudes out the x axis, with $y = 0$. Apply weight to the end, and it depresses. The governing equation is.

$$B \frac{d^2 \theta}{ds^2} = W \cos \theta, \quad \theta(0) = \frac{d\theta}{ds}(L) = 0$$

θ is the angle of depression, S is the length of the board (protruded from the wall), and W is the weight applied. And B is the 'bending stiffness' of the board. If we want to use it in terms of x, y

$$\frac{dx}{ds} = \cos \theta, \quad \frac{dy}{ds} = \sin \theta$$

This is a dimensional problem, so we non-dimensionalise it (get rid of B, W, L): let $s = L\hat{s}$

$$\begin{aligned}
B \frac{d^2 \theta}{ds^2} &= W \cos \theta, \quad \theta(0) = \frac{d\theta}{ds}(L) \\
\frac{B}{L^2} \frac{d^2 \theta}{d\hat{s}^2} &= W \cos \theta \\
\frac{d^2 \theta}{d\hat{s}^2} &= \frac{WL^2}{B} \cos \theta
\end{aligned}$$

So let $\delta = WL^2/B$ and lazily drop the hats to get

$$\frac{d^2\theta}{ds^2} = \delta \cos \theta, \quad \theta(0) = \frac{d\theta}{ds}(1) = 0$$

(also apply to the boundary conditions)

Assume δ small. So we would expect something like a short board, a small weight or a very stiff board (or some combination of these). Equation and δ assumption imply θ is small. Use change of variables:

$$\theta = \delta\phi$$

Gives

$$\begin{aligned} \frac{d^2\phi}{ds^2} &= \cos(\delta\phi), \quad \phi(0) = \frac{d\phi}{ds}(1) = 0 \\ \frac{d^2\phi}{ds^2} &= 1 - \frac{1}{2}(\delta\phi^2) + \frac{1}{24}(\delta\phi)^4 + \dots, \quad \phi(0) = \frac{d\phi}{ds}(1) = 0 \end{aligned}$$

Perturbation series for ψ Basically if you run through, you find that there are no odd powers of δ .

$$\phi = \phi_0 + \delta^2\phi_1 + \delta^4\phi_2 + \delta^6\phi_3 + \dots$$

Leading order term

$$\frac{d\phi_0}{ds^2} = 1, \quad \phi_0(0) = \frac{d\phi_0}{ds} = 0$$

So $\frac{d\phi_0}{ds} = s + c \implies c = -1$

$$\phi_0 = \frac{1}{2}s^2 - s + c_2, \quad c_2 = 0$$

So we have

$$\phi_0 = \frac{1}{2}s^2 - s$$

We could continue to get the next term but basically theres no point. If we want to get x, y

$$\frac{dx}{ds} = \cos \theta, \quad \frac{dy}{ds} = \sin \theta$$

$$\frac{dx}{ds} = \cos \delta\phi, \quad \frac{dy}{ds} = \sin \delta\phi$$

For x :

$$\cos \delta\phi = \cos\left(\delta\left(\frac{1}{2}s^2 - s\right)\right) \sim 1 + \mathcal{O}(\delta^2)$$

So to leading order

$$x \sim s$$

For y :

$$\sin(\delta\phi) \sim \delta\phi + \mathcal{O}(\delta^3) = \delta\left(\frac{1}{2}s^2 - s\right)$$

$$y \sim \delta\frac{1}{6}s^3 - \frac{\delta}{2}s^2$$

For flow around a cylinder and an exact solution Uniform flow speed U and cylinder has radius a

$$\nabla^2\phi = 0$$

Where $r > a$ With boundary conditions (no slip)

$$n \cdot \nabla\phi = 0$$

At $r = a$ and

$$\phi \sim Ur \cos \theta, \quad r \rightarrow \infty$$

The exact solution is

$$\phi(r, \theta) = U(r + a^2/r) \cos \theta$$

Now if we consider a perturbed cylinder (so its not a circle but slightly squashed). An ellipse given by

$$r = a(1 + \epsilon \cos 2\theta)$$

Problem is now

$$\nabla^2 \phi = 0, \quad r > a(1 + \epsilon \cos 2\theta)$$

With the boundary conditions

$$n \cdot \nabla \phi = 0, \quad r = a(1 + \epsilon \cos 2\theta)$$

And the same uniform flow as before asymptotically as $r \rightarrow \infty$

We essentially want to linearise around the boundary with an equivalent problem with $r > a$ instead of $r > a(1 + \epsilon \cos 2\theta)$

Solve:

Say you have $f(x, y)$ on $y = a + h(x)$. Now take the taylor expansion of $f(x, a + h(x))$ about $y = a$.

$$\begin{aligned} f(x, a + h(x)) &= f(x, a) \\ &+ (a + h(x) - a)f'(x, a) \\ &+ (a + h(x) - a)^2 f''(x, a) + \dots \end{aligned}$$

Gives

$$f(x, a + h(x)) = f(x, a) + h(x)f'(x, a) + h^2(x)f''(x, a)$$

Let the surface of the ellipse be represented by

$$g(r, \theta) = r - a(1 + \epsilon f(\theta))$$

We need to obtain the normal vector, n

$$n = \frac{\nabla G}{|\nabla G|}$$

Note that ∇ in cylindrical coordinates is

$$\nabla \frac{\partial}{\partial r} e_r + \frac{1}{r} \frac{\partial}{\partial \theta} e_\theta$$

$$\nabla G = \nabla(r - a(1 + \epsilon f(\theta))) = e_r - a\epsilon f'(\theta)e_\theta$$

On $r = a(1 + \epsilon f(\theta))$

$$\therefore \nabla G_{r=..} = e_r - \frac{a\epsilon f'(\theta)}{a(1 + \epsilon f(\theta))} = e_r - \frac{\epsilon f'(\theta)}{1 + \epsilon f(\theta)}$$

Now use the geometric series

$$\nabla G_{r=..} = e_r - \epsilon f'(\theta)(1 - \epsilon f(\theta) + \mathcal{O}(\epsilon^2))$$

$$|\nabla G_{r=..}| = \sqrt{1^2 + \frac{\epsilon^2 f'^2(\theta)}{(1 + \epsilon f(\theta))^2}}$$

Use a binomial expansion

$$\begin{aligned}\frac{1}{|\nabla G|} &= 1 - \frac{1}{2}\epsilon^2 f'^2(\theta)(1 - \epsilon f(\theta) + \dots)^2 + \mathcal{O}(\epsilon^4) \\ n = \frac{\nabla G}{|\nabla G|} &= (e_r - \epsilon f'(\theta)(1 - \epsilon f(\theta) + \mathcal{O}(\epsilon^2))e_\theta) \times (1 - \mathcal{O}(\epsilon^2)) \\ n &= e_r - \epsilon f'(\theta)e_\theta + \mathcal{O}(\epsilon^2)\end{aligned}$$

So the no slip condition gives

$$n \cdot \nabla \phi|_{r=a(1+\epsilon f(\theta))} = 0$$

$$\begin{aligned}LHS &= (e_r - (\epsilon f'(\theta) + \mathcal{O}(\epsilon^2))e_\theta) \cdot (e_r \frac{\partial \phi}{\partial r} + \frac{1}{r} \frac{\partial \phi}{\partial \theta} e_\theta) \\ &= \frac{\partial \phi}{\partial r} - \epsilon f'(\theta) \frac{\partial \phi}{\partial \theta} \frac{1}{a} (1 - \epsilon f(\theta) + \mathcal{O}(\epsilon^2)) \\ &= \frac{\partial \phi}{\partial r} - \epsilon \frac{f'(\theta)}{a} \frac{\partial \phi}{\partial \theta} + \mathcal{O}(\epsilon^2)\end{aligned}$$

Since $\frac{1}{r} = \frac{1}{a(1+\epsilon f(\theta))}$ use geom series

$$\frac{1}{r} = \frac{1}{a}(1 - \epsilon f(\theta) + \dots)$$

Unfortunately this is still on $r = a(1 + \epsilon f)$. So we have to taylor expand the two partial derivatives

$$\begin{aligned}\frac{\partial \phi}{\partial r} \Big|_{r=a(1+\epsilon f(\theta))} &= \frac{\partial \phi}{\partial r} \Big|_{r=a} + \epsilon a f(\theta) \frac{\partial^2 \phi}{\partial r^2} \Big|_{r=a} + \mathcal{O}(\epsilon^2) \\ \frac{\partial \phi}{\partial \theta} \Big|_{r=a(1+\epsilon f(\theta))} &= \frac{\partial \phi}{\partial \theta} \Big|_{r=a} + \mathcal{O}(\epsilon)\end{aligned}$$

Now the boundary condition becomes, and sub in $f(\theta) = \cos 2\theta$

$$\begin{aligned}LHS &= \frac{\partial \phi}{\partial r} - \epsilon \frac{f'(\theta)}{a} \frac{\partial \phi}{\partial \theta} + \mathcal{O}(\epsilon^2) \\ &= \frac{\partial \phi}{\partial r} \Big|_{r=a} + \epsilon a f(\theta) \frac{\partial^2 \phi}{\partial r^2} \Big|_{r=a} - \epsilon \frac{f'(\theta)}{a} \frac{\partial \phi}{\partial \theta} \Big|_{r=a} + \mathcal{O}(\epsilon^2) \\ &= \frac{\partial \phi}{\partial r} \Big|_{r=a} + \epsilon a \cos 2\theta \frac{\partial^2 \phi}{\partial r^2} \Big|_{r=a} + \epsilon \frac{2 \sin 2\theta}{a} \frac{\partial \phi}{\partial \theta} \Big|_{r=a} + \mathcal{O}(\epsilon^2)\end{aligned}$$

On $r = a$. So now the boundary condition is just on something simple (not perturbed).

Now to solve ϕ we use a perturbation series about ϕ .

$$\phi = \phi_0 + \epsilon \phi_1 + \mathcal{O}(\epsilon^2)$$

Subject to the condition we got before and

$$\nabla^2 \phi = 0, \quad r > a$$

Leading order:

$$\nabla^2 \phi_0 = 0, \quad r > a$$

With

$$\frac{\partial \phi_0}{\partial r} = 0, \quad r = a, \quad \phi \sim U r \cos(\theta)$$

Which is identical to the unperturbed problem

$$\phi_0 = U \left(r + \frac{a^2}{r} \right) \cos(\theta)$$

At order ϵ

$$\nabla^2 \phi_1 = 0, \quad r > a$$

Subject to the BC:

$$\frac{\partial \phi_1}{\partial r} + a \cos 2\theta \frac{\partial^2 \phi_0}{\partial r^2} + \frac{2}{a} \sin 2\theta \frac{\partial \phi_0}{\partial \theta} = 0, \quad r = a$$

With $\phi_1 \sim o(1)$ at $r = a$.

Rewrite the first BC:

$$\begin{aligned} \frac{\partial \phi_1}{\partial r} &= -a \cos 2\theta \frac{\partial^2 \phi_0}{\partial r^2} - \frac{2}{a} \sin 2\theta \frac{\partial \phi_0}{\partial \theta} \\ &= -a \cos 2\theta U \frac{2a^2}{r^3} \cos \theta + \frac{2}{a} \sin 2\theta \sin \theta U \left(r + \frac{a^2}{r} \right) \\ \frac{\partial \phi_1}{\partial r} \Big|_{r=a} &= -2U (\cos 2\theta \cos \theta - 2 \sin 2\theta \sin \theta) \\ &= -2U (\cos 2\theta \cos \theta - 2 \sin 2\theta \sin \theta) \\ &= U (\cos(\theta) - 3 \cos(3\theta)) \end{aligned}$$

Last step obtained using:

$$\begin{aligned} &\cos \theta \cos 2\theta - 3 \cos \theta \cos 2\theta + \sin \theta \sin 2\theta + 3 \sin \theta \sin 2\theta \\ &= (\cos \theta \cos 2\theta + \sin \theta \sin 2\theta) - 3 (\cos \theta \cos 2\theta - \sin \theta \sin 2\theta) \\ &= \cos(2\theta - \theta) - 3 \cos(2\theta + \theta) \\ &= \cos(\theta) - 3 \cos(3\theta) \end{aligned}$$

So our boundary condition is now

$$\frac{\partial \phi_1}{\partial r} \Big|_{r=a} = U (\cos(\theta) - 3 \cos(3\theta))$$

Use separation of variables $\phi_1 = R(r)T(\theta)$

$$\begin{aligned} \nabla^2 \phi_1 &= \frac{\partial^2 \phi_1}{\partial r^2} + \frac{1}{r} \frac{\partial \phi_1}{\partial r} + \frac{1}{r^2} \frac{\partial^2 \phi_1}{\partial \theta^2} = 0, \quad r \geq a \\ R''T + \frac{1}{r} R'T + \frac{1}{r^2} RT'' &= 0 \\ \frac{T''}{T} &= -r^2 \frac{R''}{R} + -r \frac{R'}{R} + R = c^2 \\ T'' &= -c^2 T, \quad r^2 \frac{\partial^2 R}{\partial r^2} + r \frac{\partial R}{\partial r} - c^2 R = 0 \end{aligned}$$

Solve the T equation

$$\frac{\partial R}{\partial r} \Big|_{r=a} \implies T(\theta) = U (\cos \theta - \cos 3\theta)$$

(the sine coefficients are trivially zero) Which gives

$$c^2 = 1^2, \quad \text{or} \quad 3^2$$

For $c = \pm 1$

$$R_1(r) = c_1 r + \frac{c_2}{r}$$

For $c = \pm 3$

$$R_2(r) = c_3 r^3 + \frac{c_4}{r^3}$$

So ϕ_1 :

$$\phi_1 = (c_1 r + \frac{c_2}{r}) \cos \theta + (c_3 r^3 + \frac{c_4}{r^3}) \cos 3\theta$$

Note we had the far field condition, $\phi_1 \sim o(1)$ as $r \rightarrow \infty$ So the r and r^3 coefficients must be zero.

$$\phi_1 = \frac{c_2}{r} \cos \theta + \frac{c_4}{r^3} \cos 3\theta$$

$$\begin{aligned} \left. \frac{\partial \phi_1}{\partial r} \right|_{r=a} &= -\frac{c_2}{r^2} \cos \theta - 3 \frac{c_4}{r^3} \cos 3\theta \\ &= -\frac{c_2}{a^2} \cos \theta - \frac{3c_4}{a^3} \cos 3\theta = U(\cos \theta - 3 \cos 3\theta) \end{aligned}$$

So $-c_2/a^2 = U$ and $c_4/a^3 = U$. So $c_2 = -Ua^2$ and $c_4 = Ua^4$.

Therefore

$$\phi_1 = \frac{-Ua^2}{r} \cos \theta + \frac{Ua^4}{r^3} \cos 3\theta$$

And so we have

$$\phi = \phi_0 + \epsilon \phi_1 + \mathcal{O}(\epsilon^2) = U(r + \frac{a^2}{r}) \cos(\theta) + \epsilon \left(\frac{-Ua^2}{r} \cos \theta + \frac{Ua^4}{r^3} \cos 3\theta \right) + \mathcal{O}(\epsilon^2)$$

We can't really see what the error is here since we don't have a canonical solution to compare to. We want to know when $\phi_1 = \mathcal{O}(\phi_0)$

Deep water waves in 1D (free surface problem): So considering a water bed with small amplitude waves on the surface of the water. This is a prototypical example of a free-surface problem. Where the shape of the boundary is determined as part of the solution. So the surface instead of $y = 0$ we will have

$$y = \epsilon h(x, t)$$

So assume $\epsilon \ll 1$ and $h = \mathcal{O}(1)$. The velocity is described by laplaces equation

$$\nabla^2 \phi = 0, \quad y < \epsilon h(x, t)$$

The boundary conditions on the free-surface are a kinematic condition

$$\frac{\partial \phi}{\partial y} = \epsilon \left(\frac{\partial h}{\partial t} + \frac{\partial \phi}{\partial x} \frac{\partial h}{\partial x} \right), \quad y = \epsilon h(x, t)$$

Which states the normal to the velocity of the water is equal to the normal velocity if the surface. We also have the bernoulli equation as a condition

$$\frac{\partial \phi}{\partial t} + \frac{1}{2} |\nabla \phi|^2 + gy = 0, \quad y = \epsilon h(x, t)$$

Lets take a perturbation series solution: expand ϕ as a perturbation series - change the domain $y = \epsilon h(x, t)$ to be more usable (transform into the normal one), and then solve recursively.

$$\phi = \phi_0 + \epsilon \phi_1 + \mathcal{O}(\epsilon^2)$$

Using the kinematic condition, we get (collect powers of ϵ)

$$\frac{\partial \phi_0}{\partial y} = 0 \implies \phi_0 = 0$$

Now obtaining ϕ_1 (start with the kinematic equation at order ϵ)

$$\frac{\partial \phi_1}{\partial y} = \frac{\partial h}{\partial t}, \quad y = \epsilon h(x, t)$$

Expand (linearise) about the unperturbed interface, $y = 0$.

$$\begin{aligned} \frac{\partial \phi_1}{\partial y} \Big|_{y=h(x,t)} &= \frac{\partial \phi_1}{\partial y} \Big|_{y=0} + \epsilon h(x, t) \frac{\partial^2 \phi_1}{\partial y^2} \Big|_{y=0} \\ \frac{\partial \phi_1}{\partial y} &= \frac{\partial h}{\partial t} + \mathcal{O}(\epsilon^2), \quad y = 0 \end{aligned}$$

Now the bernoulli condition. Note that we are collecting orders ϵ^1

$$\frac{\partial \phi_1}{\partial t} + gh(x, t) = 0, \quad y = \epsilon h(x, t)$$

So taylor series on $\frac{\partial \phi_1}{\partial t}$

$$\frac{\partial \phi_1}{\partial t} \Big|_{y=\epsilon h(x,t)} = \frac{\partial \phi_1}{\partial d} t \Big|_{y=0} + \epsilon h(x, t) \frac{\partial^2 \phi_1}{\partial y \partial t} + \mathcal{O}(\epsilon^2)$$

Since we are doing this to leading order

$$\frac{\partial \phi_1}{\partial t} \Big|_{y=\epsilon h(x,t)} = \frac{\partial \phi_1}{\partial d} t \Big|_{y=0}$$

So the bernoulli condition becomes

$$\frac{\partial \phi_1}{\partial t} + gh = 0, \quad y = 0$$

Let $h = ae^{i(kx - \omega t)}$. And seek a solution to the problem for this h .

Implies

$$\phi_1 = f(y)e^{i(kx - \omega t)}$$

Put this into laplace's equation

$$\begin{aligned} \nabla^2 \phi_1 &= (-k^2 f + f'')e^{i(kx - \omega t)} = 0 \\ (-k^2 f + f'') &= 0 \\ \implies f''/f &= k^2 \\ \implies f &= be^{|k|y} \end{aligned}$$

For physical solutions, we can't have ϕ blow up. So we have to find ω given a, k such that it doesn't.

Using the kinematic condition

$$\begin{aligned} \frac{\partial \phi_1}{\partial y} &= \frac{\partial h}{\partial t}, \quad y = 0 \\ b|k|e^{|k|y}e^{i(kx - \omega t)} &= -i\omega ae^{i(kx - \omega t)} \\ b|k| &= -i\omega a \\ b &= -\frac{i\omega a}{|k|} \end{aligned}$$

So

$$\phi_1 = -\frac{i\omega a}{|k|} e^{ik|y|} e^{i(kx-\omega t)}$$

Now using the bernoulli condition

$$\begin{aligned}\frac{\partial \phi_1}{\partial t} + gh &= 0 \\ -\frac{\omega^2 a}{|k|} e^{ik|y|} e^{i(kx-\omega t)} + gae^{i(kx-\omega t)} &= 0 \\ -\frac{\omega^2}{|k|} + g &= 0 \\ \omega &= \sqrt{g|k|}\end{aligned}$$

So ω has no dependence on b, a . ω is real. So h will be purely oscillatory. We would expect the term to die down over time if we included surface tension (waves would decay) which is the realistic analogue.

Interpretation is that disturbances neither grow or decay.

Case study: hollow fibre bioreactor.

An important application area in mathematical biology is tissue engineering - making artificial tissues. It consists of a hollow outer tube and an inner permeable tube. Cells are seeded around the outside of the inner tube. Fluid containing nutrients is passed inside the inner tube. The idea is that the nutrients will pass through the permeable tube wall into the space containing the cells. Note the relative lengths mean the length of the tube is really large versus very small relative heights.

The approach is to develop a model for fluid flow in the inner tube and then couple it into a model for the nutrient transfer.

Find conditions etc.

Reduce the model, and non-dimensionalise.

Assumption of slenderness; aspect ratio of the tube is small

$$\epsilon = d/L \approx 2 \times 10^{-3} \ll 1$$

Full equations

$$\nabla \cdot \mathbf{u}_l = 0, \quad \rho \left(\frac{\partial \mathbf{u}_l}{\partial t} + (\mathbf{u}_l \cdot \nabla) \mathbf{u}_l \right) = -\nabla p_l + \mu \nabla^2 \mathbf{u}_l$$

Apply the scalings $i = l, m, e$ and $\epsilon = d/L$

$$r = d\tilde{r}, \quad z = L\tilde{z}, \quad u_{i,z} = U\tilde{u}_{i,z}, \quad u_{i,r} = \epsilon U\tilde{u}_{i,r}, \quad p = P_i\tilde{p} + P_0$$

Dropping the tildes and get the reduced equations:

$$\frac{1}{r} \frac{\partial}{\partial r} (ru_{l,r}) + \frac{\partial u_{l,z}}{\partial z} = 0, \quad \frac{1}{r} \frac{\partial}{\partial r} \left(r \frac{\partial u_{l,z}}{\partial r} \right) = \frac{dp_l}{dz}$$

Project: Find a research paper which uses asymptotic and/or perturbation methods (ideally in an area you're interested in) and write a 'brief' report

- Background - provide some background to the application
- Summary - summarise the mathematical approach
- Use of asymptotics/perturbation methods - give some detail on the usage
- Redo some working - repeat a few steps of working from the paper (fill in gaps)

Should be short - 2-3 pages.

0.5 Boundary Layers and Matching

Recall the dominant balance for singular perturbation problems. E.g.

$$\epsilon x^5 + x = 1$$

Which changes the behaviour of the solutions. Note that the real was ‘small’ and the complex roots were ‘big’

A similar kind of ‘multi-scale’ structure is often seen in the solutions to singularly perturbed DEs. We use these problems where there is a rapid change of behaviour in one region, but slowly in another. Hence the idea of a boundary layer. We usually impose the no slip condition at the boundary to avoid this problem.

A different distinguished limit of a governing equation is valid in different regions of the solution domain. To solve these problems we need to

1. Construct solutions which are (asymptotically) valid in the various parts of the domain. Typically an **inner solution** near the edge of a domain, and an **outer solution** in the rest of the domain
2. Join these solutions by using **asymptotic matching** - use the fact that their regions of validity overlap.

Not all singularly perturbed DEs exhibit boundary layers but it is common. Asymptotic matching can be used in other contexts, and not just for boundary layers.

Consider the ODE

$$\epsilon \frac{d^2 y}{dx^2} + 2 \frac{dy}{dx} + y = 0$$

As $\epsilon \rightarrow 0$ with BCs

$$y(0) = 0, \quad y(1) = 1$$

This is singularly perturbed since setting $\epsilon = 0$ changes the order of the problem. The full 2nd order DE has an exact closed form solution

$$y(x) = \frac{e^{ax} - e^{bx}}{e^a - e^b}$$

Where

$$a = \frac{-1 + \sqrt{1 - \epsilon}}{\epsilon}, \quad b = \frac{-1 - \sqrt{1 - \epsilon}}{\epsilon}$$

Which features an $e^{-x/\epsilon}$ type dependence which is characteristic of boundary layer problems.

Lets try solving this to leading order using our asymptotic expansion

$$y = y_0 + \epsilon y_1 + \mathcal{O}(\epsilon^2)$$

$$\mathcal{O}(1) : \quad 2 \frac{dy_0}{dx} + y_0 = 0, \quad y_0(0) = 0, \quad y_0(1) = 1$$

$$\mathcal{O}(\epsilon) : \quad \frac{d^2 y_0}{dx^2} + 2 \frac{dy_1}{dx} + y_1 = 0, \quad y_1(0) = y_1(1) = 0$$

But we won't bother using $y_0(0) = 0$ and same for $y_1(0) = 0$ since they are outside of the region we're working with (we will show why we can do this later) Solving the first order:

$$y_0(x) = e^{(1-x)/2}$$

This is the "outer solution" since it does not work on the boundary layer, but works away from it.

To obtain the "inner solution" we need to rescale. In this case we will use $x = \epsilon X$, and let $y = Y(X)$. This will work the same way as nondimensionalisation.

$$\begin{aligned}\epsilon \frac{d^2 y}{dx^2} + 2 \frac{dy}{dx} + y &= 0 \\ \epsilon \frac{1}{\epsilon^2} \frac{d^2 Y}{dX^2} + 2 \frac{1}{\epsilon} \frac{dY}{dX} + Y &= 0 \\ \frac{d^2 Y}{dX^2} + 2 \frac{dY}{dX} + \epsilon Y &= 0\end{aligned}$$

This is no longer a singularly perturbed problem. And our solutions will only really be valid in the inner region.

Now do the same thing we did for the outer region:

$$Y = Y_0 + \epsilon Y_1 + \mathcal{O}(\epsilon^2)$$

At order 1:

$$\begin{aligned}\frac{d^2 Y_0}{dX^2} + 2 \frac{dY_0}{dX} &= 0 \\ Y_0' &= A e^{-2X} \\ Y_0 &= A e^{-2X} + B \\ Y_0 &= A (1 - e^{-2X})\end{aligned}$$

How do we determine A ? This is where the asymptotic matching comes in - we impose an extra condition. In this case we impose the **Matching condition**:

$$\lim_{x \rightarrow 0} y_0(x) = \lim_{X \rightarrow \infty} Y_0(X)$$

$$\begin{aligned}\lim_{X \rightarrow \infty} e^{(1-x)/2} &= \lim_{x \rightarrow 0} e^{(1-x)/2} \\ A &= e^{1/2}\end{aligned}$$

So our solution for Y_0 becomes

$$Y_0 = e^{1/2} (1 - e^{-2X})$$

Note that A is the $y_{overlap}$ which is used in the composite solution too.

Now we have 2 functions separately. We want to join them by taking advantage of the fact they overlap. We do this by constructing a **composite solution**.

$$\begin{aligned}y_{comp} &= Y(X) + y(x) - y_{overlap} \\ y_{comp,0} &= Y_0(X) + y_0(x) - y_{overlap} \\ &= e^{(1-x)/2} + e^{1/2} (1 - e^{-2X}) - e^{1/2} \\ &= e^{(1-x)/2} + e^{-1/2-2X} \\ &= e^{(1-x)/2} + e^{-1/2-2x/\epsilon}\end{aligned}$$

But if we plug in $x = 1$

$$y_{comp,0}(1) = e^0 - e^{1/2-2/\epsilon} \neq 1$$

Which means the boundary solution at $x = 1$ is no longer satisfied. Although, for $\epsilon \rightarrow 0$, it does approach 1.

Step-by-step process

- Find outer solution: Try a regular perturbation solution

$$y(x) = y_0(x) + \epsilon y_1(x) + \dots$$

If (as in this example) we can't satisfy all boundary conditions via this method, then we have boundary layers and require further analysis

- Determine the **distinguished limits**: Use a dominant balance analysis to determine appropriate scalings - each balance corresponds to either the outer solution, or an inner solution. In the previous example we rescaled only the independent variable ($x = \epsilon X$), but sometimes it is necessary to do the same for the dependent variable.
- Having determined the presence (and location) of a boundary layer, seek a regular perturbation series solution to the rescaled problem.

$$Y(x) = Y_0 + \epsilon Y_1(x) + \dots$$

- Matching: Apply an asymptotic matching to connect the two solutions. The outer limit of the inner solution has to be equal to the inner limit of the outer solution. More sophisticated conditions are necessary at higher order
- Construct composite solution

Another Second-order ODE problem

$$\epsilon \frac{d^2 y}{dx^2} + \frac{dy}{dx} = \cos x$$

With $\epsilon \rightarrow 0$ over $0 \leq x \leq \pi$ and the BCs

$$y(0) = 2, \quad y(\pi) = -1$$

Start with the outer solution:

$$y = y_0 + \epsilon y_1 + \dots$$

To leading order:

$$\frac{dy_0}{dx} = \cos x$$

Subject to $y_0(0) = 2$ and $y_0(\pi) = -1$ Gives

$$y_0 = \sin x + A$$

Which boundary condition do we apply here? Either $A = 2$ (apply $x = 0$ bc) and there is a boundary layer at $x = \pi$, or

$A = -1$ (apply $x = \pi$ bc) and there is a boundary layer at $x = 0$

But we can't have both. So let's determine the distinguished limit:

Let $x - x^* = \delta_1(\epsilon)X$ (where x^* is the location of the boundary layer, and δ_1 is some power function of ϵ)

$$x = x^* + \delta_1 X$$

Also let $y = \delta_2(\epsilon)Y$

Equation and BCs become

$$\epsilon \frac{\delta_2}{\delta_1^2} \frac{d^2 Y}{dX} + \frac{\delta_2}{\delta_1} \frac{dY}{dX} = \cos(x^* + \delta_1 X)$$

BCs:

$$\delta_2 Y(0) = 2, \quad \delta_2 Y(\pi) = -1$$

Since the the left and right hand sides of the BCs have no epsilon dependence on the RHS, we have

$$\delta_2 = 1$$

So now rewrite the equation with $\delta_2 = 1$ and multiply by δ_1

$$\epsilon \frac{d^2 Y}{dX} + \delta_1 \frac{dY}{dX} = \delta_1^2 \cos(x^* + \delta_1 X)$$

So we want to find δ_1 to give at least a 2 term balance.

- $\delta_1 Y' \sim \delta_1^2 \cos(\cdot)$ neglect $\epsilon Y''$ This implies

$$\delta_1 \sim \delta_1^2 \implies \delta_1 \sim 1$$

This is the outer solution case that we have already done!

- $\epsilon Y'' \sim \delta_1^2 \cos(\cdot)$, neglect $\delta_1 Y'$ This implies

$$\epsilon \sim \delta_1^2 \implies \delta_1 \sim \epsilon^{1/2}$$

But then we have a contradiction since the $\delta_1 Y'$ term will now dominate the balance.

- $\epsilon Y'' \sim -\delta_1 Y'$, neglect $\delta_1^2 \cos(\cdot)$

$$\delta_1 \sim \epsilon \implies \delta_1^2 \sim \epsilon^2$$

Which is valid.

So we let $\delta_1 = \epsilon$ (we could scale this by a constant, but its not necessary).

$$\frac{d^2 Y}{dX^2} + \frac{dY}{dX} = \epsilon \cos(x^* + \epsilon X)$$

Subject to

$$Y(0) = 2, \quad Y(\pi) = -1$$

Inner solution

$$Y(X) = Y_0 + \epsilon Y_1 + \dots$$

To leading order:

$$Y_0'' + Y_0' = 0$$

Gives

$$Y_0 = B + Ce^{-X}$$

We need to determine x^* before we can apply one of the BCs to this. I.e. $x^* = 0$ or $x^* = \pi$. We have 2 potential outcomes. Usually you can observe which one will be blatantly wrong, but we will show both:

- $x^* = 0$

$$\lim_{x \rightarrow 0} y_0 = \lim_{X \rightarrow \infty} Y_0$$

BL is at $x^* = 0$

- $x^* = \pi$

$$\lim_{x \rightarrow \pi} y_0 = \lim_{X \rightarrow -\infty} Y_0$$

Note that $X \rightarrow -\infty$ of Y_0 will shoot off to infinity as $e^{-(-\infty)} = \infty$

So we have

$$y_0(x) = \sin(x) - A, \quad Y_0(X) = B + Ce^{-X}$$

$$y_0(\pi) = -1, \quad Y_0(0) = 2$$

$$A = -1$$

$$B = 2 - C$$

Gives

$$y_0(x) = \sin(x) - 1, \quad Y_0(X) = 2 + C(e^{-X} - 1)$$

Now use the matching condition to find C .

$$\begin{aligned} \lim_{x \rightarrow 0} y_0(x) &= \lim_{X \rightarrow \infty} Y_0(X) \\ \lim_{x \rightarrow 0} \sin(x) - 1 &= \lim_{X \rightarrow \infty} 2 + C(e^{-X} - 1) \\ -1 &= 2 - C \\ C &= 3 \end{aligned}$$

Note this means $y_{overlap} = -1$ So

$$Y_0(X) = 2 + 3(e^{-X} - 1)$$

Now get the composite solution

$$\begin{aligned} y_{comp} &= y_0(x) + Y_0(X) - y_{overlap} \\ &= \sin x - 1 + 3e^{-X} - 1 + 1 \\ &= \sin x + 3e^{-\frac{x}{\epsilon}} - 1 \end{aligned}$$

Mike says that apparently

$$e^{-f(x)/\epsilon}$$

Is really common boundary layer behaviour

Validity? So why does this stuff work? What are the regions of validity for y_0 and Y_0 ? Well y_0 is valid when its asymptotic to the behaviour in the overlap (apparently) I.e. in the region of x where (Outer)

$$\sin x - 1 \sim -1$$

$$x - 1 \sim -1$$

$$x \ll 1$$

What about for Y_0 ?

(Inner)

$$\begin{aligned} 3e^{-x/\epsilon} - 1 &\sim -1 \\ 3(1 - \frac{x}{\epsilon} + \dots) - 1 &\sim -1 \\ \epsilon &\ll x \end{aligned}$$

So the overlap region is valid when

$$\epsilon \ll x \ll 1$$

One more second-order ODE example

$$\epsilon \frac{\partial^2 y}{\partial x^2} - (2 - x^2)y = -1, \quad \epsilon \rightarrow 0$$

Subject to $y'(0) = 0$ and $y(1) = 0$ Outer solution:

$$(2 - x^2)y_0 = -1 \implies y_0(x) = \frac{1}{2 - x^2}$$

this already satisfies $y'_0(0) = 0$ automatically. So this means there is no boundary layer at $y = 0$, and since there are no parameters to change to suit the other boundary condition, there must be a BL at $x^* = 1$.

Set $x = 1 + \delta_1(\epsilon)X$ and $y = \delta_2(\epsilon)Y$. Since $y(1) = 0$ gives no information about the order of the function at the boundary, we have to use the matching condition to find δ_2 .

$$\lim_{x \rightarrow 1} y_0 = \lim_{X \rightarrow -\infty} \delta_2 Y$$

Implies that $\delta_2 = 1$ since $\lim_{x \rightarrow 1} y_0 = 1 = \mathcal{O}(1)$.

So now if we continue

$$\begin{aligned} \frac{\epsilon}{\delta_1^2} Y'' - (2 - (1 + \delta_1 X)^2)Y &= -1 \\ \frac{\epsilon}{\delta_1^2} Y'' - ((1 - 2\delta_1 X - \delta_1^2 X^2)Y &= -1 \end{aligned}$$

Since we are looking at a boundary layer, it is perfectly reasonable (and recommended) to make the assumption that δ_1 is small, i.e. Assuming that $\delta_1 \ll 1$ we write

$$\frac{\epsilon}{\delta_1^2} Y'' - Y \sim -1 \implies \delta_1 = \epsilon^{1/2}$$

The rescaled problem is then

$$Y'' - (1 - 2\epsilon^{1/2}X - \epsilon X^2)Y = -1, \quad Y(0) = 0$$

Since we have $\epsilon^{1/2}$ in this, we seek a perturbation series solution of form

$$Y = Y_0(X) + \epsilon^{1/2}Y_1(X) + \epsilon Y_2(X) + \dots$$

So to leading order

$$Y_0'' - Y_0 = -1, \quad Y_0(X=0) = 0$$

(the boundary condition is since $x = 1 + \delta_1 X$) Which has general solution

$$Y_0(X) = Ae^{-X} + Be^X + 1$$

Hold off on satisfying the BC until after matching.

$$\begin{aligned}\lim_{x \rightarrow 1} y_0(x) &= \lim_{X \rightarrow -\infty} Y_0 \\ 1 &= \lim_{X \rightarrow -\infty} Ae^{-X} + Be^X + 1\end{aligned}$$

We strictly require $A = 0$ or else the RHS will diverge. And note that $y_{overlap} = 1$ here.

Applying the final BC now gives $B = -1$ and hence

$$Y_0(X) = 1 - e^X$$

Now note $X = (x - 1)/\delta_1 = (x - 1)/\sqrt{\epsilon}$ So the composite solution is:

$$\begin{aligned}y_{comp} &= y_0 + Y_0 - y_{overlap} \\ &= \frac{1}{2 - x^2} + 1 - e^X - 1 \\ &= \frac{1}{2 - x^2} - e^{(x-1)/\sqrt{\epsilon}}\end{aligned}$$

How can we improve these solutions?

Higher-Order Matching

We have been using the matching condition of form

$$\lim_{X \rightarrow \infty} Y_0(X) = \lim_{x \rightarrow 0} y_0(x)$$

If we include more terms in the series, we have to use another procedure/rule known as Van Dyke matching. This rule is stated:

The m -term inner expansion of the n -term outer solution
matches with
the n term inner expansion of the m -term outer solution.

The process is effectively for the first line:

1. Find n terms in the outer solution
2. Rewrite the expression in terms of the inner variable
3. Simplify/Expand as necessary
4. Retain the first m terms

And the third line says

1. Find m terms in the inner solution
2. Rewrite it in terms of the outer variable
3. Simplify/Expand as necessary
4. Retain the first n terms

Matching will then involve equating the two expressions to determine any unknown coefficients.

Consider an example

$$\epsilon \frac{d^2 y}{dx^2} - \frac{dy}{dx} + y = 2x, \quad \epsilon \rightarrow 0$$

With $y(0) = -2$

$$\begin{aligned} -y'_0 + y_0 &= 2x, & y_0(0) &= -2, & y_0(1) &= 1 \\ y''_0 - y'_1 + y_1 &= 0, & y_1(0) &= 0, & y_1(1) &= 0 \end{aligned}$$

To leading order:

$$y_0 = A_0 e^x + 2x + 2$$

And then hence

$$y_1 = A_1 e^x + A_0 x e^x$$

(this involves method of undetermined coefficients) Inner problem: Let $x = x_* + \delta_1 X$ and $y = \delta_2 Y$. BCs gives $\delta_2 = 1$. Hence

$$\epsilon \frac{d^2 Y}{dX^2} - \delta_1 \frac{dY}{dX} + \delta_1^2 Y = \delta_1^2 2(x_* + \delta_1 X)$$

Distinguished limit is for $\delta_1 = \epsilon$ i.e.

$$\frac{d^2 Y}{dX^2} - \frac{dY}{dX} + \epsilon Y = \epsilon 2(x_* + \epsilon X)$$

Giving the problems

$$\begin{aligned} Y''_0 - Y'_0 &= 0, & Y_0(0) &= -2 \text{ or } Y_0(0) = 1 \\ Y''_1 - Y'_1 + Y_0 &= 2x_*, & Y_1(0) &= 0 \end{aligned}$$

Leading order:

$$Y_0 = C_0 e^X - B_0$$

Diverges if the outer limit is $X \rightarrow +\infty$. So we require $X \rightarrow -\infty$. I.e. the boundary layer is on the right at $x_* = 1$. Applying this BC gives $B_0 = C_0 - 1$ hence

$$Y_0 = C_0(e^X - 1) + 1$$

The $\mathcal{O}(\epsilon)$ inner equation becomes

$$\begin{aligned} Y''_1 - Y'_1 &= -C_0(e^X - 1) + 1 \\ \implies Y_1 &= C_1(e^X - 1)C_0X(e^X + 1) - X \end{aligned}$$

If we apply the BCs on the outer solution (little x, y) gives $A_0 = -4$ and $A_1 = 0$.

$$y_{out(2)}(x) = -4e^x + 2x + 2 - \epsilon 4x e^x$$

$$Y_{in(2)}(X) = C_0(e^X - 1) + 1 + \epsilon(C_1(e^X - 1) - C_0X(e^X + 1) - X)$$

If we were only interested in leading order: use the normal limit

$$\lim_{x \rightarrow 1} y_0 = \lim_{X \rightarrow -\infty} Y_0 \implies -4e + X = -C_0 + 1 \implies C_0 = 4e - 3$$

This is Van Dyke matching with $m = n = 1$.

If we want to do it with $m = n = 2$ The outer solution needs to be rewritten in terms of the inner variable

$$\begin{aligned} y_{out}(x) &= -4e^x x + 2x + 2 - \epsilon 4x e^x \\ y_{out}(1 + \epsilon X) &= -4e^{1+\epsilon X} + 2(1 + \epsilon X) + 2 - \epsilon 4(1 + \epsilon X)e^{1+\epsilon X} \\ y_{out(2,2)}(X) &= -4e + 4 + \epsilon(-4eX + 2X - 4e) \end{aligned}$$

We expanded $e^{\epsilon X}$ using power series, and then simplified, and we have concatenated to order $\mathcal{O}(\epsilon)$.

Now do the inner expansion in terms of the outer variable i.e. writing $X = \frac{x-1}{\epsilon}$

$$\begin{aligned} Y_{in}(X) &= C_0(e^X - 1) + 1 + \epsilon(C_1(e^X - 1) - C_0X(e^X + 1) - X) \\ Y_{in}(x) &= C_0(e^{(x-1)/\epsilon} - 1) + 1 + \epsilon\left(C_1(e^{(x-1)/\epsilon} - 1) - C_0\frac{x-1}{\epsilon}(e^{(x-1)/\epsilon} + 1) - \frac{x-1}{\epsilon}\right) \\ &= -C_0 + 1 + \epsilon\left(-C_1 - (C_0 + 1)\frac{x-1}{\epsilon}\right) \\ Y_{in(2,2)}(x) &= -C_0 + 1 - (C_0 + 1)(x - 1) + \epsilon(-C_1) \end{aligned}$$

We dropped all the exponential terms since $x \rightarrow 0$ and $\epsilon \rightarrow 0$ so they will all be negligible. To make them match, they have to be equal at each order

$$\begin{aligned} y_{out(2,2)}(X) &= Y_{in(2,2)}(x) \\ -4e + 4 + \epsilon(-4eX + 2X - 4e) &= -C_0 + 1 - (C_0 + 1)(x - 1) + \epsilon(-C_1) \\ -4e + 4 + \epsilon(-(4e - 2)X - 4e) &= -C_0 + 1 - \epsilon(-(C_0 + 1)X - C_1) \end{aligned}$$

Equating orders gives $C_0 = 4e - 3$ as before. At $\mathcal{O}(\epsilon)$ we get

$$\begin{aligned} -(4e - 2)X - 4e &= -(4e - 2)X - C_1 \\ \implies C_1 &= 4e \end{aligned}$$

The fact that the X dependence disappears means that we've done it right.

Now calculate the composite solution as we usually would. Where $y_{overlap} = y_{out(2,2)}(X)$ If you've done things right, the overlap behaviour should cancel out entirely.

$$\begin{aligned} y_{comp(2,2)} &= y_{out(2)}(x) + Y_{in(2)}(X) - y_{overlap} \\ &\vdots \\ &= -4e^x + 2x + 2 + (4e - 3)e^X + \epsilon(4xe^x - 4e^{X+1} - (4e - 3)Xe^X) \end{aligned}$$

And we can rewrite this in terms of x i.e. $X = \frac{x-1}{\epsilon}$ for a proper solution

WKBJ approximation An alternative way is to apply ansatz of the form

$$y(x) \sim \sum_{n=0}^{\infty} u_n(x)\epsilon^n + e^{-F(x)/\epsilon} \sum_{n=0}^{\infty} v_n(x)\epsilon^n$$

Which is known as WKB ansatz or Wentzel, Kramers and Brillouin Jeffreys.

Lets do a previous example up to ϵ^2

$$\epsilon \frac{d^2 y}{dx^2} + \frac{dy}{dx} = \cos x, \quad \epsilon \rightarrow 0$$

Subject to $y(0) = 2$ and $y(\pi) = -1$, over $0 \leq x \leq \pi$. Recall there was a boundary layer at $x = 0$ and we rescaled with $x = \epsilon X$, $y = Y$. Outer problem

$$\begin{aligned} y'_0 &= \cos x, & y_0(\pi) &= -1 \\ y''_0 + y'_1 &= 0, & y_1(\pi) &= 0 \\ y''_1 + y'_2 &= 0, & y_2(\pi) &= 0 \end{aligned}$$

Gives

$$y_{outer} = \sin x - 1 + \epsilon(-\cos x - 1) - \epsilon^2 \sin x + \mathcal{O}(\epsilon^2)$$

Inner solution

$$\frac{d^2 Y}{dX^2} + \frac{dY}{dX} = \epsilon \cos(\epsilon x) = \epsilon \left(1 - \epsilon^2 \frac{1}{2} X^2 + \dots \right)$$

Gives

$$\begin{aligned} Y''_0 + Y'_0 &= 0, & Y_0(0) &= 2 \\ Y''_1 + Y'_1 &= 1, & Y_1(0) &= 0 \\ Y''_2 + Y'_2 &= 0, & Y_2(0) &= 0 \end{aligned}$$

Gives

$$Y_{in}(X) = 2 + C_0(e^{-X} - 1) + \epsilon(C_1(e^{-X} - 1) + X) + \epsilon^2 C_2(e^{-X} - 1) + \mathcal{O}(\epsilon^3)$$

Matching to determine C_0 , C_1 , and C_2 . Look at

$$\begin{aligned} y_{out(3)} &= \sin(\epsilon X) - 1 + \epsilon(-\cos \epsilon X - 1) - \epsilon^2 \sin(\epsilon X) \\ &= \left(\epsilon X - \frac{1}{6} \epsilon^3 X^3 + \dots \right) - 1 + \epsilon \left(- \left(1 - \frac{1}{2} \epsilon^2 X^2 + \dots \right) - 1 \right) + \epsilon^2 (\epsilon X + \dots) \\ y_{out(3,3)}(X) &= -1 + \epsilon(X - 2) \\ y_{out(3,3)}(x) &= -1 + x - 2\epsilon \end{aligned}$$

Which is also the overlap behaviour for the composite. Now the inner in terms of the outer (using $X = \frac{x}{\epsilon}$)

$$\begin{aligned} Y_{in(3)}(x) &= 2 + C_0(e^{-x/\epsilon} - 1) + \epsilon(C_1(e^{-x/\epsilon} - 1) + \frac{x}{\epsilon}) + \epsilon^2 C_2(e^{-x/\epsilon} - 1) \\ &= 2 + C_0(-1) + \epsilon(C_1(-1) + \frac{x}{\epsilon}) + \epsilon^2 C_2(-1) + e.s.t \end{aligned}$$

$$Y_{in(3,3)}(x) = 2 - C_0 + x - \epsilon C_1 - \epsilon^2 C_2$$

Where e.s.t is exponentially small terms Matching gives:

$$\begin{aligned} y_{out(3,3)}(x) &= Y_{in(3,3)}(x) \\ -1 + x - 2\epsilon &= 2 - C_0 + x - \epsilon C_1 - \epsilon^2 C_2 \end{aligned}$$

The fact that there is an x on both sides is a good sign. Hence

$$C_0 = 3, \quad C_1 = 2, \quad C_2 = 0$$

Hence the composite solution:

$$\begin{aligned} y_{comp(3,3)} &= y_{out(3)} + Y_{in(3)} - y_{overlap} \\ &= \sin x - 1 + \epsilon(-\cos x - 1) - \epsilon^2 \sin x + 2 + 3(e^{-X} - 1) + \epsilon(2(e^{-X} - 1) + X) - (-1 + x - 2\epsilon) \\ &= \sin x - 1 + 3e^{-x/\epsilon} + \epsilon(-1 - \cos x + 2e^{-x/\epsilon}) - \epsilon^2 \sin x \end{aligned}$$

Now we're finally going to do WKBJ approximation for boundary layers

$$y(x) \sim \sum_{n=0}^{\infty} u_n(x) \epsilon^n + e^{-F(x)/\epsilon} \sum_{n=0}^{\infty} v_n(x) \epsilon^n$$

We can apply this for pretty much any perturbation/bl problem, especially if there are multiple scales.

Apply it to the example

$$\epsilon \frac{d^2 y}{dx^2} + (2x + 1) \frac{dy}{dx} + 2y = 0$$

With $\epsilon \rightarrow 0$ and $0 \leq x \leq 1$ and bcs $y(0) = 2$ and $y(1) = 1$

Leading order solution by matched asymptotics is

$$y_{comp}(x) = \frac{3}{1+2} - e^{-x/\epsilon}$$

Lets see if we can get a 'better' one using WKB.

reduce the WKB ansatz to leading order

$$y \sim u_0 + e^{-F/\epsilon} v_0$$

$$y' \sim u'_0 + e^{-F/\epsilon} v'_0 - \frac{F'}{\epsilon} e^{-F/\epsilon} (v_0 + \epsilon v_1 + \dots)$$

$$y'' \sim u''_0 + e^{-F/\epsilon} v''_0 - 2 \frac{F'}{\epsilon} e^{-F/\epsilon} v'_0 + \left(\frac{F'}{\epsilon} \right)^2 e^{-F/\epsilon} (v_0 + \epsilon v_1 + \dots) - \frac{F''}{\epsilon} e^{-F/\epsilon} v_0$$

Using the WKB ansatz and equating to various orders:

$$\mathcal{O}(1) : 0 = (2x + 1)u'_0 + 2u_0$$

$$\mathcal{O}(e^{-F(x)/\epsilon} \epsilon^{-1}) : 0 = [F' - (2x + 1)]F'v_0$$

$$\mathcal{O}(e^{-F(x)/\epsilon}) : 0 = [-2F' + 2x + 1]v'_0 + (-F'' + 2)v_0 + [F' - (2x + 1)]F'v_1$$

We know the boundary layer is at $x = 0$, so we'd like u_0 and v_0 to balance as per the composite solution. I.e. we would want $e^{-F/\epsilon} = \mathcal{O}(1)$, so $F(0) = 0$. For F to be non-trivial, the second equation gives:

$$F' = 2x + 1$$

Which gives

$$F(x) = x^2 + x$$

Solving the $\mathcal{O}(1)$ equation and applying $u_0(1) = 1$ gives

$$u_0(x) = \frac{3}{2x + 1}$$

Hence the third equation becomes

$$-(2x + 1)v'_0 = 0$$

and applying $u_0(0) + v_0 = 2$ to get $v_0 = -1$ Hence the final solution is

$$y_{WKB}(x) = \left(\frac{3}{2x + 1} - e^{-(x^2+x)/\epsilon} \right) (1 + \mathcal{O}(\epsilon))$$

This has slightly more detail than the composite solution due to the x^2 in the exponential term.

What if we considered the problem with the perturbed cylinder in a flow moving left to right. Now if instead of perturbing the cylinder, we heated the cylinder, and we want to model the temperature of the water flowing past the cylinder.

We expect the water close to the cylinder to be warm, and for that heat to carry down with the flow.

To model this, assume the diffusion of temperature is small compared to advection (i.e. a high Peclet number). giving

$$\mathbf{u} \cdot \nabla T = \epsilon \nabla^2 T, \quad r \geq 1$$

We're only solving for T since we already know

$$\mathbf{u} = \nabla \phi, \quad \phi = \left(r + \frac{1}{r}\right) \cos \theta$$

The boundary conditions are

$$T = 1, \quad r = 1, \quad \text{and} \quad T \rightarrow 0, \quad \text{as } r \rightarrow \infty$$

I.e. the temperature is fixed at 1 on the surface of the cylinder, and far away from the cylinder the temperature is 0.

Note in real life we might expect the heat to change the flow in some way.

As usual calculate the outer solution first. Lets try a perturbation series of form:

$$T(r, \theta) = T_0 + \epsilon T_1 + \mathcal{O}(\epsilon^2)$$

With $\epsilon \rightarrow 0$. This gives

$$\mathbf{u} \cdot \nabla T_0 = 0, \quad T_0(1, \theta) = 1, T_0(\infty, \theta) \rightarrow 0$$

The only acceptable solution is $T_0(r, \theta) = 0$ (since it must be constant on streamlines). And similarly for all T_n . But this doesn't satisfy $T_0(1, \theta) = 1$. Hence there is a boundary layer on $r = 1$.

The inner solution's equation is:

$$\left(1 - \frac{1}{r^2}\right) \cos \theta \frac{\partial T}{\partial r} - \left(1 + \frac{1}{r^2}\right) \frac{\sin \theta}{r} \frac{\partial T}{\partial \theta} = \epsilon \left(\frac{\partial^2 T}{\partial r^2} + \frac{1}{r} \frac{\partial T}{\partial r} + \frac{1}{r^2} \frac{\partial^2 T}{\partial \theta^2} \right)$$

Lets take a change of variables $r = 1 + \delta \rho$. We need to find out what the scaling on δ is. The equation becomes

$$\left(1 - \frac{1}{(1 + \delta \rho)^2}\right) \frac{\cos \theta}{\delta} \frac{\partial T}{\partial \rho} - \left(1 + \frac{1}{(1 + \delta \rho)^2}\right) \frac{\sin \theta}{1 + \delta \rho} \frac{\partial T}{\partial \theta} = \epsilon \left(\frac{1}{\delta^2} \frac{\partial^2 T}{\partial \rho^2} + \frac{1}{\delta(1 + \delta \rho)} \frac{\partial T}{\partial \rho} + \frac{1}{(1 + \delta \rho)^2} \frac{\partial^2 T}{\partial \theta^2} \right)$$

Expanding denominators with binomial expansions will give:

$$(2\delta\rho + \dots) \frac{\cos \theta}{\delta} \frac{\partial T}{\partial \rho} 2 - (2 + \dots) \sin \theta \frac{\partial T}{\partial \theta} = \epsilon \left(\frac{1}{\delta^2} \frac{\partial^2 T}{\partial \rho^2} + \frac{1}{\delta} (1 + \dots) \frac{\partial T}{\partial \rho} + (1 + \dots) \frac{\partial^2 T}{\partial \theta^2} \right)$$

Rewrite so all the ϵ and δ is on the RHS

$$(2\rho + \dots) \cos \theta \frac{\partial T}{\partial \rho} 2 - (2 + \dots) \sin \theta \frac{\partial T}{\partial \theta} = \frac{\epsilon}{\delta^2} \frac{\partial^2 T}{\partial \rho^2} + \frac{\epsilon}{\delta} (1 + \dots) \frac{\partial T}{\partial \rho} + \epsilon (1 + \dots) \frac{\partial^2 T}{\partial \theta^2}$$

(may be a typo)

Look at possible balances:

- $\delta = 1$ just gives the outer solution
- $\delta = \epsilon^{1/2}$ brings in the first RHS term only without causing a contradiction (so we use this)

Setting $\delta = \epsilon^{1/2}$ and introducing the inner perturbation series:

$$T = T_0 + \epsilon^{1/2}T_1 + \mathcal{O}(\epsilon)$$

To leading order:

$$2\rho \cos \theta \frac{\partial T_0}{\partial \rho} - 2 \sin \theta \frac{\partial T_0}{\partial \theta} = \frac{\partial^2 T_0}{\partial \rho^2}$$

Subject to $T_0 = 1$ on $\rho = 0$ and $T_0 = 0$ on $\rho \rightarrow \infty$ (matching condition)

There is a similarity solution of the form: (we don't need to know where this comes from)

$$T = f(\eta), \quad \eta = \frac{\rho \sin \theta}{(1 + \cos \theta)^{1/2}}$$

The leading order equation becomes

$$\frac{2\rho \cos \theta \sin \theta}{(1 + \cos \theta)^{1/2}} f' - \frac{2 \sin \theta}{(1 + \cos \theta)^{1/2}} \left(\rho \cos \theta + \frac{\rho \sin^2 \theta}{2(1 + \cos \theta)} \right) f' = \frac{\sin^2 \theta}{1 + \cos \theta} f''$$

Rearranging and simplifying:

$$\begin{aligned} -\frac{2 \sin \theta}{(1 + \cos \theta)^{1/2}} \left(\frac{\rho \sin^2 \theta}{2(1 + \cos \theta)} \right) f' &= \frac{\sin^2 \theta}{1 + \cos \theta} f'' \\ -\frac{\rho \sin \theta}{(1 + \cos \theta)^{1/2}} f' &= f'' \\ -\eta f' &= f'' \end{aligned}$$

Simple separable first order ODE!

Hence

$$f(\eta) = A \int_0^\infty e^{-u^2/2} du + B$$

Applying the matching condition $f \rightarrow 0$ as $\eta \rightarrow \infty$ gives $B = 0$. The other condition $f = 1$ on $\eta = 0$ ($r = 1$) gives $A = \sqrt{2/\pi}$

$$T_0 = \sqrt{\frac{2}{\pi}} \int_\eta^\infty e^{-u^2/2} du, \quad \eta = \epsilon^{1/2} \frac{(r-1) \sin \theta}{(1 + \cos \theta)^{1/2}}$$

0.6 Multi-Scale Problems

Boundary Layer problems typically feature multiple scales acting in different regions of a solution domain (inner & outer regions). Many problems of interest feature two different scales occurring simultaneously.

Some example phenomena:

- Mechanical properties - plywood, sponges, fibreglass, whose overall behaviour depends on the small scale structure.
- Biological tissues compromised of cells

- Propagation of waves through a region which contains small obstacles

The methods used for these are **multiscale methods** or equivalently **the method of multiple scales**.

Say we have a solution $y(t)$ of the form $y(\tau, T)$, where $\tau = t$ and $T = \epsilon t$ to represent the fast and slow scales. Under this change of variables we get

$$\frac{d}{dt} = \frac{d\tau}{dt} \frac{\partial}{\partial \tau} + \frac{dT}{dt} \frac{\partial}{\partial T} = \frac{\partial}{\partial \tau} + \epsilon \frac{\partial}{\partial T}$$

And then if we want the second derivative we get

$$\frac{d^2}{dt^2} = \dots = \frac{\partial^2}{\partial \tau^2} + 2\epsilon \frac{\partial^2}{\partial \tau \partial T} + \epsilon^2 \frac{\partial^2}{\partial T^2}$$

This then permits analysis of problems which are not otherwise amenable to the techniques of the perturbation problems already considered. Lets look at the Van der Pol oscillator.

The Van der Pol equation is:

$$\frac{d^2 y}{dt^2} + \epsilon(y^2 - 1) \frac{dy}{dt} + y = 0$$

With $\epsilon \ll 1$, $y(0) = 0$ and $y'(0) = 0$. We will see that for small ϵ the solution displays behaviour on two time scales simultaneously: rapid oscillations (fast scale) combined with a gradual change in amplitude (slow scale).

If we tried a regular perturbation solution: $y = y_0 + \epsilon y_1 + \mathcal{O}(\epsilon^2)$

$$y_0'' + y_0 = 0$$

$y_0(0) = 1$ and $y_0'(0) = 0$ Hence

$$y_0(t) = \cos t$$

At $\mathcal{O}(\epsilon)$

$$\begin{aligned} y_1'' + y_1 &= -(y_0^2 - 1)y_0' \\ y_1'' + y_1 &= -\sin^3 t \end{aligned}$$

$y_1(0) = 0, y_1'(0) = 0$.

We would use variation of parameters here (using the wronskian)

$$y_1 = A(t) \cos t + B(t) \sin t$$

Where

$$A(t) = - \int \frac{1}{W} \sin t (-\sin^3 t) dt \text{ and } B(t) = \int \frac{1}{W} \cos t (-\sin^3 t) dt$$

And

$$W = \det \begin{pmatrix} \cos t & \sin t \\ -\sin t & \cos t \end{pmatrix} = \cos^2 t + \sin^2 t = 1$$

Which finally gives

$$y_1 = \frac{3t \cos t}{8} - \frac{9 \sin t}{32} - \frac{\sin 3t}{32}$$

This doesn't match the true solution since it levels out with time, whereas this solution expands in time (forever). There is 'resonance' in the equation. We have **secular or resonant** terms

in the equations. Namely terms that on integration give erroneous growth. Multiple scale analysis prevents this issue.

$$\frac{d^2 y}{dt^2} + \epsilon(y^2 - 1)\frac{dt}{dt} + y = 0$$

Now a perturbation series for the two variables

$$y(t) \equiv y(\tau, T) = y_0(\tau, T) + \epsilon y_1(\tau, T) + \dots$$

$$\begin{aligned}\frac{d}{dt} &= \frac{\partial}{\partial \tau} + \epsilon \frac{\partial}{\partial T} \\ \frac{d^2}{dt^2} &= \frac{\partial^2}{\partial \tau^2} + 2\epsilon \frac{\partial^2}{\partial \tau \partial T} + \epsilon^2 \frac{\partial^2}{\partial T^2}\end{aligned}$$

Giving the equation:

$$\frac{\partial^2 y}{\partial \tau^2} + 2\epsilon \frac{\partial^2 y}{\partial \tau \partial T} + \epsilon^2 \frac{\partial^2 y}{\partial T^2} + \epsilon(y^2 - 1)\left(\frac{\partial y}{\partial \tau} + \epsilon \frac{\partial y}{\partial T}\right) + y = 0$$

At leading order:

$$\frac{\partial^2 y_0}{\partial \tau^2} + y_0 = 0$$

This is the same as before EXCEPT this is a PDE for y . With $y_0(t=0) = 1$ and $y'_0(t=0) = 0$
The initial conditions become

$$\begin{aligned}y_0 &= 1 \\ \frac{\partial y_0}{\partial \tau} + \epsilon \frac{\partial y_0}{\partial T} &= 0 \implies \frac{\partial y_0}{\partial \tau} = 0 \text{ at } \mathcal{O}(\epsilon)\end{aligned}$$

Solving the PDE for y_0 :

$$y_0(\tau, T) = R(T) \cos(\tau + \theta(T))$$

And the boundary conditions give:

$$\begin{aligned}y_0(0, 0) &= 1 \implies R(0) = 1 \\ \frac{\partial y_0(0, 0)}{\partial \tau} &= 0 \implies R(T)(-\sin(\theta(T))) \implies \theta(0) = 0\end{aligned}$$

Now at order $\mathcal{O}(\epsilon)$:

$$\begin{aligned}\frac{\partial^2 y_1}{\partial \tau^2} + y_1 &= -2 \frac{\partial y_0}{\partial \tau \partial T} - (y^2 - 1) \frac{\partial y_0}{\partial \tau} \\ \frac{\partial y_0}{\partial \tau} &= -R(t) \sin(\tau + \theta(T)) \\ \frac{\partial y_0}{\partial \tau \partial T} &= -R'(T) \sin(\tau + \theta(T)) - R(T) \cos(\tau + \theta(T)) \theta'(T)\end{aligned}$$

$$\begin{aligned}
\frac{\partial^2 y_1}{\partial \tau^2} + y_1 &= -2 \frac{\partial y_0}{\partial \tau \partial T} - (y^2 - 1) \frac{\partial y_0}{\partial \tau} \\
\frac{\partial^2 y_1}{\partial \tau^2} + y_1 &= 2R' \sin(\tau + \theta) + 2R\theta' \cos(\tau + \theta) + (R^2 \cos^2(\tau + \theta) - 1)(-R \sin(\tau + \theta)) \\
&\vdots \\
\frac{\partial^2 y_1}{\partial \tau^2} + y_1 &= 2R\theta' \cos(\tau + \theta) + (2R' + \frac{R^3}{4} - R) \sin(\tau + \theta) + \frac{R^3}{4} \sin(3(\tau + \theta))
\end{aligned}$$

We won't solve this! Only use it to obtain information about R and θ . Since we don't want unbounded growth we require these forcing terms to be 0. I.e. solve

$$\begin{aligned}
2R\theta' &= 0 \\
2R' + \frac{R^3}{4} - R &= 0
\end{aligned}$$

For nontrivial solutions we have $\theta' = 0$, and hence $\theta = c$. And

$$\begin{aligned}
2R' + \frac{R^3}{4} - R &= 0 \\
R' &= \frac{R(4 - R^2)}{8} \\
R &= \frac{2}{(1 + 3e^{-T})^{1/2}}
\end{aligned}$$

Using the initial condition $R(0) = 1$. To satisfy the other boundary condition, $\theta(T) = k\pi$ and for simplicity we set $\theta = 0$ Hence

$$\begin{aligned}
y_0(\tau, T) &= R(T) \cos(\tau + \theta(T)) \\
&= \frac{2 \cos(\tau)}{(1 + 3e^{-T})^{1/2}} \\
y_0(t) &= \frac{2 \cos t}{(1 + 3e^{-\epsilon t})^{1/2}}
\end{aligned}$$

The key steps in the solution were:

1. Made a change of variables to account for fast/slow scales
2. Apply to the governing equation
3. Removal of resonant terms from the next-to leading order governing equation

That process featured some slightly messy algebra. There is a method which is a little more straight forward (for the same problem:

At $\mathcal{O}(1)$ we had

$$\frac{\partial^2 y_0}{\partial \tau^2} + y_0 = 0$$

An alternative solution to this PDE is

$$y_0 = A(T)e^{i\tau} + \bar{A}(T)e^{-i\tau}$$

Where \bar{A} is the complex conjugate to A .

$$\begin{aligned}\frac{\partial^2 y_1}{\partial \tau^2} + y_1 &= -(y_0^2 - 1) \frac{\partial y_0}{\partial \tau} - \frac{\partial y_0}{\partial \tau \partial T} \\ &= -(A^2 e^{i2\tau} + 2A\bar{A} + \bar{A}^2 e^{-i2\tau} - 1) (iA(t)e^{i\tau} - i\bar{A}e^{-i\tau}) - i(A'e^{i\tau} - \bar{A}'e^{-i\tau}) \\ &= (-iA' - i2A^2\bar{A} + iA + iA^2\bar{A}) e^{i\tau} \\ &\quad + (stuff2) e^{-i\tau} + (stuff3)\end{aligned}$$

We need to set these coefficient functions for $e^{i\tau}$ to zero.

$$-i(A' + A^2\bar{A} + A) = 0$$

Which should give

$$A' = \frac{A(4 - |A|^2)}{8}$$

Let $A = R(T)e^{-\theta(T)}$, and should give us the same solution as before.

0.6.1 Asymptotic Homogenisation

Another method for multiple scales is when we only really care about the large scale behaviour - to derive 'effective' governing equations for the behaviour of systems which have complicated small-scale behaviour.

Example derivation of an effective governing equation for a 1D composite material:

$$E \frac{du}{dx} = 1$$

But if

$$E \equiv E(x, \frac{x}{\epsilon})$$

Then we have a large scale and a small scale to work with. With $u(0) = 0, u(1) = \alpha$, Where u is the displacement of the solid from a reference point (in this case an undeformed state), x is the Lagrangian co-ordinate along the beam, and E is a Young's modulus. If E is constant, the equation is simple to solve (linear elasticity). If E is a function of position, and varies along multiple scales? Let $\xi = x/\epsilon$

$$\begin{aligned}\frac{d}{dx} &= \frac{\partial}{\partial x} + \frac{1}{\epsilon} \frac{\partial}{\partial \xi} \\ E(x, \xi) \left(\frac{\partial u}{\partial x} + \frac{1}{\epsilon} \frac{\partial u}{\partial \xi} \right) &= 1\end{aligned}$$

Let $u(x) \equiv u(x, \xi)$ and hence

$$\frac{du}{dx} = \frac{\partial u}{\partial x} + \frac{1}{\epsilon} \frac{\partial u}{\partial \xi}$$

Governing equation becomes

$$\begin{aligned}E(x, \xi) \left(\frac{\partial u}{\partial x} + \frac{1}{\epsilon} \frac{\partial u}{\partial \xi} \right) &= 1 \\ \implies E(x, \xi) \left(\epsilon \frac{\partial u}{\partial x} + \frac{\partial u}{\partial \xi} \right) &= \epsilon\end{aligned}$$

Letting $u(x, \xi) = u_0 + \epsilon u_1 + \dots$ gives (to leading order)

$$\frac{\partial u_0}{\partial \xi} = 0 \implies u_0(x, \xi) \equiv u_0(x)$$

Leading order only varies on the macroscale! (this is a good thing!!) To order $\mathcal{O}(\epsilon)$

$$\begin{aligned} E(x, \xi) \left(\frac{\partial u_0}{\partial x} + \frac{\partial u_1}{\partial \xi} \right) &= 1 \\ \implies \frac{du_0}{dx} + \frac{\partial u_1}{\partial \xi} &= \frac{1}{E(x, \xi)} \end{aligned}$$

Integrating over one microscale period gives (noting that ξ goes from 0 to 1)

$$\int_0^1 \frac{du_0}{dx} d\xi + \int_0^1 \frac{\partial u_1}{\partial \xi} d\xi = \int_0^1 \frac{1}{E(x, \xi)} d\xi$$

And since u_0 is only a function of x we get

$$\frac{du_0}{dx} \int_0^1 d\xi + [u_1]_{\xi=0}^{\xi=1} = \int_0^1 \frac{1}{E(x, \xi)} d\xi$$

We have assumed that u is periodic in ξ $u_1(x, 0) = u_1(x, 1)$ so

$$\frac{du_0}{dx} = \int_0^1 \frac{1}{E(x, \xi)} d\xi$$

And rearranging gives:

$$\frac{1}{\int_0^1 \frac{1}{E(x, \xi)} d\xi} \frac{du_0}{dx} = 1$$

Where

$$\frac{1}{\int_0^1 \frac{1}{E(x, \xi)} d\xi} =: E_{eff}(x)$$

Is the **effective** modulus for the homogenised equation. Note that this is an ODE in the macroscale variable x , with all the microscale detail incorporated into the integral of E_{eff} and noting that E_{eff} is the *harmonic mean* of $E(x, \xi)$. Lets calculate E_{eff} for

$$E(x, \xi) = \begin{cases} 1, & 0 < \xi < 1/2 \\ 0.1 + 0.5x^2, & 1/2 < \xi < 1 \end{cases}$$

Integrating over the reciprocal:

$$\begin{aligned} \int_0^1 [1/E(x, \xi)] d\xi &= \int_0^{1/2} d\xi + \int_{1/2}^1 \frac{1}{0.1 + 0.5x^2} d\xi \\ &= \frac{1}{2} \left(1 + \frac{1}{0.1 + 0.5x^2} \right) = \frac{1.1 + 0.5x^2}{2(0.1 + 0.5x^2)} \end{aligned}$$

Hence

$$E_{eff} = \frac{2(0.1 + 0.5x^2)}{1.1 + 0.5x^2}$$

0.6.2 Homogenisation in 2D, with periodic microstructure

Many practical applications for homogenisation involve periodic microstructure (small scale is periodic). We now can extend this to multiple spacial dimensions.

Antiplane strain, $w(x, y)$. We have a 3D bar and deform is such that two components of displacement are zero, and the remaining component is w . Strain is governed by

$$\nabla \cdot (\mu \nabla w) = 0$$

Here we have antiplane strain $w \equiv w(x, y)$ and the shear modulus $\mu \equiv \mu(x, y)$. We consider the case of small scale periodic structure in μ , corresponding to a composite material.

We consider a composite material with two material scales. E.g. pencils glued together - the pencil lead, and the wood are the two materials. In this case μ is periodic in cross-section, and features small-scale variation. Practical example could be optical fibre cables (multi-core), steel reinforced concrete pillars, ... Introduce $\mu \equiv \mu(x, y, \xi, \eta)$ where $(\xi, \eta) = (x, y)/\epsilon$. We assume periodicity in ξ with period 1, and η by period b , so

$$\mu(x, y, \xi + 1, \eta) = \mu(x, y, \xi, \eta), \quad \mu(x, y, \xi, \eta + b) = \mu(x, y, \xi, \eta)$$

We're assuming there are only two values for μ . One in the wood, and one in the lead.

Derivation of the effective equation:

Similarly let $w \equiv w(x, y, \xi, \eta)$ with same periodicity as μ . Apply the chain rule to get

$$\nabla \rightarrow \nabla_x + \frac{1}{\epsilon} \nabla_\xi$$

Where

$$\begin{aligned} \nabla_x &= \frac{\partial}{\partial x} \mathbf{i} + \frac{\partial}{\partial y} \mathbf{j} \\ \nabla_\xi &= \frac{\partial}{\partial \xi} \mathbf{i} + \frac{\partial}{\partial \eta} \mathbf{j} \end{aligned}$$

$$\nabla_\xi \cdot (\mu \nabla_\xi w) + \epsilon [(\nabla_\xi \cdot (\mu \nabla_x w) + \nabla_x \cdot (\mu \nabla_\xi w))] + \epsilon^2 \nabla_x \cdot (\mu \nabla_x w) = 0$$

Lets consider one microscale cell (to ultimately average over it, like we did in 1D). Say our representative cell has domain

$$0 < \xi < 1, \quad 0 < \eta < b$$

Periodicity of w means that its ξ and η derivaties are also periodic.

$$\begin{aligned} w(x, y, 1, \eta) &= w(x, y, 0, \eta), \quad w(x, y, \xi, b) = w(x, y, \xi, 0) \\ \frac{\partial w}{\partial \xi}(x, y, 1, \eta) &= \frac{\partial w}{\partial \xi}(x, y, 0, \eta), \quad \frac{\partial w}{\partial \eta}(x, y, \xi, b) = \frac{\partial w}{\partial \eta}(x, y, \xi, 0) \end{aligned}$$

Seek solution of form:

$$w \sim w_0 + \epsilon w_1 + \epsilon w_2$$

Substituting this into the governing equation gives:

$$\begin{aligned} \mathcal{O}(1) : 0 &= \nabla_\xi \cdot (\mu \nabla_\xi w_0) \\ \mathcal{O}(\epsilon) : 0 &= \nabla_\xi \cdot (\mu \nabla_\xi w_1) + [\nabla_\xi \cdot (\mu \nabla_x w_0) + \nabla_x \cdot (\mu \nabla_\xi w_0)] \\ \mathcal{O}(\epsilon^2) : 0 &= \nabla_\xi \cdot (\mu \nabla_\xi w_2) + [\nabla_\xi \cdot (\mu \nabla_x w_1) + \nabla_x \cdot (\mu \nabla_\xi w_1)] + \nabla_x \cdot (\mu \nabla_x w_0) \end{aligned}$$

We won't solve w_1 or w_2 , we just use the information from them.

Leading order:

$$0 = \nabla_\xi \cdot (\mu \nabla_\xi w_0)$$

Subject to its boundary conditions. Easy to see that the conditions are satisfied when w is independent to the microscale variables. I.e.

$$w_0 \equiv w_0(x, y)$$

Which is what we want in homogenisation. This is actually the unique solution (but we won't show it here).

At $\mathcal{O}(\epsilon)$ - using the fact that $w_0 \equiv w_0(x, y)$ (hence dropping the micro terms)

$$0 = \nabla_\xi \cdot (\mu \nabla_\xi w_1) + \nabla_\xi \cdot (\mu \nabla_x w_0)$$

Expanding the ∇ 's and some rearrangement:

$$\frac{\partial}{\partial \xi} \left(\mu \frac{\partial w_1}{\partial \xi} \right) + \frac{\partial}{\partial \eta} \left(\mu \frac{\partial w_1}{\partial \eta} \right) = -\frac{\partial \mu}{\partial \xi} \frac{\partial w_0}{\partial x} - \frac{\partial \mu}{\partial \eta} \frac{\partial w_0}{\partial y}$$

Two things to note:

1. The form of this derivative is a PDE (linear, elliptic) for w_1
2. Equation has periodic solution if RHS has zero mean, that is

$$\int_0^1 \int_0^b \left(\frac{\partial \mu}{\partial \xi} \frac{\partial w_0}{\partial x} + \frac{\partial \mu}{\partial \eta} \frac{\partial w_0}{\partial y} \right) d\xi d\eta = 0$$

We won't prove this last statement (but will assume it - would use divergence theorem apparently)

Solution of w_1 has form

$$w_1(x, y, \xi, \eta) = W^{(1)}(x, y, \xi, \eta) \frac{\partial w_0}{\partial x} + W^{(w)}(x, y, \xi, \eta) \frac{\partial w_0}{\partial y}$$

Substituting this into the $\mathcal{O}(\epsilon)$ equation and equating coefficients of $\frac{\partial w_0}{\partial x}$ and $\frac{\partial w_0}{\partial y}$ to get

$$\begin{aligned} \frac{\partial}{\partial \xi} \left(\mu \frac{\partial W^{(1)}}{\partial \xi} \right) + \frac{\partial}{\partial \eta} \left(\mu \frac{\partial W^{(1)}}{\partial \eta} \right) &= -\frac{\partial \mu}{\partial \xi} \\ \frac{\partial}{\partial \xi} \left(\mu \frac{\partial W^{(2)}}{\partial \xi} \right) + \frac{\partial}{\partial \eta} \left(\mu \frac{\partial W^{(2)}}{\partial \eta} \right) &= -\frac{\partial \mu}{\partial \eta} \end{aligned}$$

Now the PDE is 2 PDEs for the coefficient functions, with the corresponding periodic boundary conditions.

This problem only depends on the microscale. Has unique periodic solutions and for a given $\mu(x, y, \xi, \eta)$ it can be solved numerically (if we wanted to).

So $\mathcal{O}(1)$ has given us a macro scale problem, while $\mathcal{O}(2)$ is a microscale problem.

For $\mathcal{O}(\epsilon^2)$ We assume w_2 is periodic, and so the rhs (below) has to have zero mean. We won't solve it but use it.

$$\nabla_\xi \cdot (\mu \nabla_\xi w_2) = -\nabla_\xi \cdot (\mu \nabla_x w_1) - \nabla_x \cdot (\mu \nabla_\xi w_1) - \nabla_x \cdot (\mu (\nabla_x w_0))$$

Taking the integrals, we can see the first RHS term is identically zero. We require that the $\frac{\partial}{\partial x}$ and $\frac{\partial}{\partial y}$ terms be zero.

$$0 = - \int_0^1 \int_0^b \left(\frac{\partial}{\partial x} \left(\mu \frac{\partial w_1}{\partial \xi} + \mu \frac{\partial w_0}{\partial x} \right) + \frac{\partial}{\partial y} \left(\mu \frac{\partial w_1}{\partial \eta} + \mu \frac{\partial w_0}{\partial y} \right) \right) d\xi d\eta$$

Substituting the thing we had for w_1 (i.e. with the capital W 's)

$$0 = - \int_0^1 \int_0^b \left(\frac{\partial}{\partial x} \left(\mu \left(\frac{\partial W^{(1)}}{\partial \xi} + 1 \right) \frac{\partial w_0}{\partial x} + \mu \frac{\partial W^{(2)}}{\partial y} \right) + \frac{\partial}{\partial y} \left(\mu \frac{\partial w_1}{\partial \eta} + \mu \frac{\partial w_0}{\partial y} \right) \right) d\xi d\eta$$

A homogenised equation for $w_0(x, y)$ is

$$\begin{aligned} \frac{\partial}{\partial x} \left(\bar{\mu}_{11} \frac{\partial w_0}{\partial x} \right) + \frac{\partial}{\partial x} \left(\mu_{12} \frac{\partial w_0}{\partial y} \right) + \\ \frac{\partial}{\partial y} \left(\bar{\mu}_{21} \frac{\partial w_0}{\partial x} \right) + \frac{\partial}{\partial y} \left(\bar{\mu}_{22} \frac{\partial w_0}{\partial y} \right) = 0 \end{aligned}$$

Where

$$\begin{aligned} \bar{\mu}_{11} &= \int_0^1 \int_0^b \mu \left(\frac{\partial W^{(1)}}{\partial \xi} + 1 \right) d\eta d\xi, & \bar{\mu}_{21} &= \int_0^1 \int_0^b \mu \frac{\partial W^{(1)}}{\partial \eta} d\eta d\xi \\ \bar{\mu}_{22} &= \int_0^1 \int_0^b \mu \left(\frac{\partial W^{(2)}}{\partial \eta} + 1 \right) d\eta d\xi, & \bar{\mu}_{12} &= \int_0^1 \int_0^b \mu \frac{\partial W^{(2)}}{\partial \xi} d\eta d\xi \end{aligned}$$

To actually apply this procedure for a given μ :

- Solve the microscale problem to get the coefficient functions $W^{(1)}, W^{(2)}$
- Use these functions to obtain the effective moduli $\bar{\mu}_{11}, \bar{\mu}_{12}, \bar{\mu}_{21}$, and $\bar{\mu}_{22}$
- Solve the homogenised equation to obtain the effective macroscale behaviour

We would then continue this by picking a particular μ .

Solving the W equations for the microscale, we can make a change of variables

$$\begin{aligned} \frac{\partial}{\partial \xi} \left(\mu \frac{\partial W^{(1)}}{\partial \xi} \right) + \frac{\partial}{\partial \eta} \left(\mu \frac{\partial W^{(1)}}{\partial \eta} \right) &= -\frac{\partial \mu}{\partial \xi} \\ \frac{\partial}{\partial \xi} \left(\mu \frac{\partial W^{(2)}}{\partial \xi} \right) + \frac{\partial}{\partial \eta} \left(\mu \frac{\partial W^{(2)}}{\partial \eta} \right) &= -\frac{\partial \mu}{\partial \eta} \end{aligned}$$

Say $W^{(1)} = \phi^{(1)} - \xi$

$$\begin{aligned} \frac{\partial}{\partial \xi} \left(\mu \frac{\partial W^{(1)}}{\partial \xi} \right) + \frac{\partial}{\partial \eta} \left(\mu \frac{\partial W^{(1)}}{\partial \eta} \right) &= -\frac{\partial \mu}{\partial \xi} \\ \frac{\partial}{\partial \xi} \left(\mu \frac{\partial \phi^{(1)}}{\partial \xi} - \mu \right) + \frac{\partial}{\partial \eta} \left(\mu \frac{\partial \phi^{(1)}}{\partial \eta} \right) &= -\frac{\partial \mu}{\partial \xi} \\ \frac{\partial}{\partial \xi} \left(\mu \frac{\partial \phi^{(1)}}{\partial \xi} \right) + \frac{\partial}{\partial \eta} \left(\mu \frac{\partial \phi^{(1)}}{\partial \eta} \right) &= 0 \end{aligned}$$

And you would do a similar thing for $W^{(2)}$.

Some points:

- Solving the microscale problem only needs to be done once per material so even though it can be computationally challenging it is worth doing!
- Often there are micro-structural symmetries making life easier
- Easy to extend it to three dimensional problems with a similar procedure.
- A significant complication in doing this is for elasticity - it requires tensors (or going to rank 4)

0.7 Integrals

Asymptotic evaluation of integrals! Particularly those of form

$$I_1(x) = \int_a^b f(t)e^{x\phi(t)} dt I_2(x) = \int_a^b f(t)e^{ix\psi(t)} dt I_3(x) = \int_C f(t)e^{x\phi(t)} dt$$

Why do we care about these? They come up in

- Solving DEs with transforms
- Approximating the PDF from the MGF in stats (we won't cover that)

We will focus on solving DEs of course. Consider the heat eqn

$$\psi_t = \psi_{xx}, \quad -\infty < x < \infty, \quad t > 0$$

With BCs $\psi \rightarrow 0$ as $|x| \rightarrow \infty$ and initial data $\psi(x, 0) = \psi_0(x)$. Fourier transform gives:

$$\psi(x, t) = \frac{1}{2\pi} \int_{-\infty}^{\infty} b_0(k) e^{ikx - k^2 t} dk$$

Where

$$b_0 = \int_{-\infty}^{\infty} e^{-ikx} \psi_0(x) dx$$

This is great to have a closed form solution, but this isn't entirely useful here. For example how does this behave for large t ? We can't simply interpret this from the integrals. So we will try asymptotics.

First step: use integration by parts on 'Laplace-type integrals' of form

$$I(x) = \int_a^b f(t) e^{x\phi(t)} dt$$

to determine the behaviour for $x \rightarrow \infty$

Consider the example

$$\begin{aligned} I(x) &= \int_0^{\infty} \frac{e^{-xt}}{(1+t^2)^2} dt \\ &= \left[\frac{e^{-xt}}{-x} \frac{1}{(1+t^2)^2} \right]_0^{\infty} - \int_0^{\infty} \frac{e^{-xt}}{-x} \frac{-4t}{(1+t^2)^3} dt \\ &= \frac{1}{x} + \mathcal{O}(1/x^3) \end{aligned}$$

We can argue this last step by bringing out the x term and considering that it will be largest for the $t = 0$ point. Or we can write it as an asymptotic relation

$$I(x) \sim \frac{1}{x}, \quad x \rightarrow \infty$$

And you would find the order of the remainder term through some argument or directly evaluating the integral.

Sometimes integration by parts doesn't work. It works if

- Requires $\phi(t)$ is monotonic
- There are no fractional powers

Sits easy to use, and we can approximate the error, but it doesn't always work. Consider

$$\begin{aligned} I(x) &= \int_0^\infty e^{-xt^2} dt \\ &= \int_0^\infty \frac{-1}{2xt} \left(-2xte^{-xt^2} \right) \\ &= \left[\frac{e^{-xt^2}}{-2xt} \right]_0^\infty - \int_0^\infty \frac{e^{-xt^2}}{2xt^2} dt \end{aligned}$$

But the first one fails for $t = 0$. We know there is an exact solution

$$\int_0^\infty e^{-xt^2} dt = \frac{\sqrt{\pi}}{2\sqrt{x}}$$

Since there is a \sqrt{x} term, it fails. It will also fail the dominant bit of the integrand is in the interior (i.e. between 0 and ∞)

One technique to evaluate these integrals more generally, is using Laplace's Method. It makes use of the fact that the most important contributions to the integral come from the regions where the integrand is largest.

Example:

$$I(x) = \int_0^{10} \frac{e^{-xt}}{(1+t)} dt$$

Consider the integrand. As we increase x the integrand gets really sharp, so all of the area under the curve is around small t . So we can kinda say its asymptotic to it So lets split the range of integration

$$\int_0^\epsilon \frac{e^{-xt}}{(1+t)} dt + \int_\epsilon^{10} \frac{e^{-xt}}{(1+t)} dt$$

We assume here that $x^{-1} \ll \epsilon \ll 1$ (small but not too small). We will explain the choice later

The second term is $\mathcal{O}(e^{-x\epsilon})$ and so is negligible compared to the first term as $x \rightarrow \infty$.

$$I(x) \sim \int_0^\epsilon \frac{e^{-xt}}{(1+t)} dt, \quad x \rightarrow \infty$$

We make the change of variables, letting $s = xt$

$$I(x) \sim \int_0^{x\epsilon} \frac{e^{-s}}{1+s/x} \frac{1}{x} ds$$

Taylor expand the fraction

$$\begin{aligned}\frac{1}{1+s/x} &= \sum_{n=0}^{\infty} \frac{(-s)^n}{x^n} \\ I(x) &\sim \frac{1}{x} \int_0^{x\epsilon} e^{-s} \sum_{n=0}^{\infty} \frac{(-s)^n}{x^n} ds \\ &= \sum_{n=0}^{\infty} \frac{1}{x^{n+1}} \int_0^{x\epsilon} e^{-s} (-s)^n ds\end{aligned}$$

Use

$$\int_0^{x\epsilon} e^{-s} (-s)^n ds \gg \int_{x\epsilon}^{\infty} e^{-s} (-s)^n ds$$

So we can add that back on

$$\begin{aligned}I(x) &\sim \sum_{n=0}^{\infty} \frac{1}{x^{n+1}} \left[\int_0^{x\epsilon} e^{-s} (-s)^n ds + \int_{x\epsilon}^{\infty} e^{-s} (-s)^n ds \right] \\ &\sim \sum_{n=0}^{\infty} \frac{1}{x^{n+1}} \int_0^{\infty} e^{-s} (-s)^n ds \\ &\sim \sum_{n=0}^{\infty} \frac{1}{x^{n+1}} (-1)^n n!\end{aligned}$$

So the steps were shortly:

1. Find the dominant contribution
2. Split the integral into dominant and small part
3. Drop the small part
4. Use a Taylor series
5. Unsplit (re-add) the small part
6. Tidy

A really useful result in this is **Watson's Lemma**. We actually used this above. For integrals of the form

$$I(x) = \int_0^b f(t) e^{-xt} dt$$

Where $f(t)$ is continuous over $0 \leq t \leq b$ and is represented by the asymptotic series

$$f(t) \sim t^{\alpha} \sum_{n=0}^{\infty} a_n t^{\beta n}, \quad t \rightarrow 0^+$$

With $\alpha > -1$ and $\beta > 0$ (for convergence at $t = 0$). Additionally, if $b = \infty$ we require $f(t) \ll e^{ct}$ as $t \rightarrow \infty$ for positive constant c . If this holds then

$$I(x) \sim \sum_{n=0}^{\infty} \frac{a_n \Gamma(\alpha + \beta n + 1)}{x^{\alpha + \beta n + 1}}, \quad \text{as } x \rightarrow \infty$$

This is just a formula, so it simply needs to be applied. The hard part is expanding $f(t)$ as the asymptotic series. Sometimes we need the binomial series

$$(1+t)^\alpha = \sum_{n=0}^{\infty} \frac{\Gamma(\alpha+1)}{\Gamma(n+1)\Gamma(\alpha-n+1)} t^n$$

Examples

$$I(x) = \int_0^5 \frac{e^{-xt}}{1+t^2} dt$$

So we need to expand $f(t) = \frac{1}{1+t^2}$ as an asymptotic series around $t = 0$.

$$\frac{1}{1+t^2} = 1 - t^2 + t^4 - \dots = \sum_{n=0}^{\infty} (-1)^n (t^2)^n$$

So $\alpha = 0$ $a_n = (-1)^n$ and $\beta = 2$. Hence

$$I(x) \sim \sum_{n=0}^{\infty} \frac{(-1)^n \Gamma(2n+1)}{x^{2n+1}} = \sum_{n=0}^{\infty} \frac{(-1)^n (2n)!}{x^{2n+1}}$$

Another example, the non-standard modified bessel function $K_0(x)$

$$K_0(x) = e^{-x} \int_0^{\infty} (t^2 + 2t)^{-1/2} e^{-xt} dt$$

Here $f(t) = (t^2 + 2t)^{-1/2}$. Use binomial

$$f(t) = (2t)^{-1/2} \sum_{n=0}^{\infty} \frac{\Gamma(-\frac{1}{2}+1)}{\Gamma(n+1)\Gamma(-\frac{1}{2}-n+1)} \left(\frac{t}{2}\right)^n$$

And then plug that into $I(x)$

Lets consider the most general form of **Laplace's method** for evaluating

$$I(x) = \int_a^b f(t) e^{x\phi(t)} dt \quad \text{as } x \rightarrow \infty$$

The key idea is that the dominant contribution is where $\phi(t)$ is largest.

Lets come up with a leading-order approximation when $\phi(t)$ has a maximum at $t = a$.

Outline for a max in $\phi(t)$ for $t = a$

1. Split the integral to 'zoom' in on a neighbourhood near the maximum point of $\phi(t)$ in the interval (so $t = a$):

$$\begin{aligned} & \int_a^b f(t) e^{x\phi(t)} dt \quad \text{as } x \rightarrow \infty \\ &= \int_a^{a+\epsilon} f(t) e^{x\phi(t)} dt + \int_{a+\epsilon}^b f(t) e^{x\phi(t)} dt, \quad \text{as } x \rightarrow \infty \end{aligned}$$

The first integral we will say is $\mathcal{O}(e^{x\phi(a)})$. The second $\mathcal{O}(e^{x\phi(a+\epsilon)})$.

$$\begin{aligned} \phi(a+\epsilon) &= \phi(a) + \epsilon\phi'(a) + \dots \\ \implies e^{x\phi(a+\epsilon)} &\approx e^{x\phi(a)} e^{\epsilon x\phi'(a)} \end{aligned}$$

So the second is actually $\mathcal{O}(e^{x\phi(a)} e^{\epsilon x\phi'(a)})$. Since it was a maximum, $\phi'(a) < 0$, and hence the second part is small provided

$$\epsilon x \phi'(a) \ll 1 \implies \epsilon x \gg 1$$

2. Assume the second part is negligible, with the restriction

$$\epsilon \gg x^{-1}$$

Hence

$$I(x) \sim \int_a^{a+\epsilon} f(t) e^{x\phi(t)} dt$$

3. Taylor expand $f(t)$ and $\phi(t)$

$$\phi(t) = \phi(a) + (t-a)\phi'(a) + \dots$$

$$f(t) = f(a) + (t-a)f'(a) + \dots$$

$$I(x) \sim \int_a^{a+\epsilon} (f(a) + \dots) e^{x(\phi(a) + (t-a)\phi'(a) + (t-a)^2\phi''(a)/2 + \dots)} dt$$

4. Since the integral is with respect to t , take out constants.

$$I(x) \sim f(a) e^{x\phi(a)} \int_a^{a+\epsilon} (\dots) e^{x(t-a)\phi'(a) + (t-a)^2\phi''(a)/2 + \dots} dt$$

5. Rescale the integration variable Let $x(t-a) = s$

$$I(x) \sim \frac{f(a) e^{x\phi(a)}}{x} \int_0^{\epsilon x} (1 + \dots) e^{s\phi'(a) + \frac{s^2}{x}\phi''(a) + \dots} ds$$

As $x \rightarrow \infty$ all the $\frac{1}{x}$ terms inside the exponentials go to zero.

$$I(x) \sim \frac{f(a) e^{x\phi(a)}}{x} \int_0^{\epsilon x} (1 + \dots) e^{s\phi'(a)} ds$$

This step is only true provided that for the top end of the integral:

$$\frac{(\epsilon x)^2}{x} \ll 1 \implies \epsilon \ll x^{-1/2}$$

So we require

$$x^{-1} \ll \epsilon \ll x^{-1/2}$$

6. Replace the upper limit with $x = \infty$ to zoom out again. And lastly, noting that $\phi'(a) < 1$

$$\begin{aligned} I(x) &\sim \frac{f(a) e^{x\phi(a)}}{x} \int_0^\infty e^{s\phi'(a)} ds \\ &= \frac{f(a) e^{x\phi(a)}}{x\phi'(a)} \left[e^{s\phi'(a)} \right]_0^\infty \\ &= -\frac{f(a) e^{x\phi(a)}}{x\phi'(a)} \end{aligned}$$

7. Evaluate the integral.

In practice we can just copy paste the formula.

If the upper limit is on the other end we just drop the minus sign

$$I(x) \sim \frac{f(b)e^{x\phi(b)}}{x\phi'(b)}$$

If we have the upper limit for an interior point:

We now have to split into 3 integrals. But we note that $\phi'(c) = 0$ and $\phi''(c) < 0$ This would give us slightly different restrictions.

$$\epsilon \gg x^{-1/2}$$

And

$$\epsilon \ll x^{-1/3}$$

integration limits become $\pm\infty$ And evaluate as before.

The three possibilities:

- Max at $t = a$

$$I(x) \sim -\frac{f(a)e^{x\phi(a)}}{x\phi'(a)}$$

- Max at $t = b$

$$I(x) \sim \frac{f(b)e^{x\phi(b)}}{x\phi'(b)}$$

- Max at $t = c$

$$I(x) \sim \frac{\sqrt{2\pi}f(c)e^{x\phi(c)}}{\sqrt{-x\phi''(c)}}$$

Sometimes the maximum is not entirely clear. For example

$$I(x) = \int_0^\infty e^{-xt - \frac{1}{t}} dt$$

We can deal with this using a change of variables.

We refer to these as **movable maxima**.

$$e^{-xt - \frac{1}{t}} = e^{-(xt + \frac{1}{t})}$$

I.e.

$$\begin{aligned} f(t; x) &= xt + \frac{1}{t} \\ f'(t; x) &= x - \frac{1}{t^2} \end{aligned}$$

The maximum will be for $t = \frac{1}{\sqrt{x}}$.

So this suggests we should try a change of variables. Let $t = \frac{s}{\sqrt{x}}$ and $dt = \frac{ds}{\sqrt{x}}$

$$\frac{1}{\sqrt{x}} \int_0^\infty e^{-\sqrt{x}(s + \frac{1}{s})} ds$$

Which is a Laplace form (just pretend $x = \sqrt{x}$).

This has a max at $s = 1$. So we'd use the central formula.

Another example is Stirling's formula

$$\Gamma(x+1) = \int_0^\infty e^{-t} t^x dt$$

We can rewrite:

$$e^{-t} t^x = e^{-t} e^{x \log t} = e^{-t+x \log t}$$

Apply a change of variables again

$$t = sx$$

And go through the mechanics, giving

$$\Gamma(n+1) \sim \sqrt{2\pi x} \left(\frac{x}{e}\right)^x$$

Consider Fourier integrals

$$I(x) = \int_a^b f(t) e^{ix\psi(t)} dt$$

for $x \rightarrow \infty$. We approximate them by the **method of stationary phase**.

For $\psi'(c) = 0$ with $a < c < b$, and $\psi'(t) \neq 0$ for $a \leq t < c$ and $c < t \leq b$, we have

$$I(x) \sim \frac{\sqrt{2\pi} f(c) e^{ix\psi(c)} e^{\pm i\pi/4}}{x^{1/2} |\psi''(c)|^{1/2}}$$

With $e^{i\pi/4}$ if $\psi''(c) > 0$ and $e^{-i\pi/4}$ if $\psi''(c) < 0$.

Note that ψ is not the cause of oscillation, but $e^{ix\psi}$ is.

Outline method: for an interior stationary point $\psi(t) = 0$ at $t = c$

1. Split the integral to zoom in on the neighbourhood near the maximum of $\psi(t)$ ($t = c$)
2. Assume the other parts are negligible
3. Taylor expand $f(t)$ and $\psi(t)$
4. Rescale the integration variable. This gives

$$\epsilon \ll x^{-1/3}$$

5. Replace upper and lower limits with $\pm\infty$ to zoom out This introduces algebraically small errors.
6. Evaluate the integral, this gives the restriction

$$\epsilon \gg x^{-1/2}$$

Since this isn't fantastic we have a different way to handle it

Lets generalise Laplace integrals to the complex plane. Integrals of form

$$I(x) = \int_C f(t) e^{x\phi(t)} dt$$

Where C is a contour in the complex t -plane, and $f(t)$ and $\phi(t)$ are analytic. Apply the **method of steepest descents** to approximate the behaviour as $x \rightarrow \infty$.

The basic principle is essentially the same as Laplace's method - look for the dominant localised contribution from the integrand. For Laplace's method it was the maximum of $\phi(t)$, but since we're in complex plane this doesn't work.

The dominant contributions will come from **saddle points**.

Background complex variable information. Since $\phi(t)$ is analytic we have

$$\phi(t) = u(\xi, \eta) + iv(\xi, \eta)$$

Where $t = \xi + i\eta$. The Cauchy-Riemann equations tell us that

$$u_\xi = v_\eta, \quad u_\eta = -v_\xi, \quad \implies \nabla^2 u = u_{\eta\eta} + u_{\xi\xi} = 0$$

A maximum or minimum in $u(\xi, \eta)$ requires $u_{\xi\xi}u_{\eta\eta} > 0$, which can't happen here.

Analytic functions can grow/undulate/etc. But the points where $\frac{d\phi}{dt} = 0$ (stationary points) are saddle points.

We can deform contours in the complex plane however we want, provided we have the correct start and end, and don't go through any discontinuities, etc..

Ideally we will avoid oscillations in the integrand, and pick an integrand such that

$$\text{Im}(\phi) = v(\xi, \eta) = \text{const}$$

Additionally we'd like there to be a point which has a dominant contribution, like in Laplace's method. Such a contour will

1. Goes through a saddle point: where $\phi'(t) = 0$
2. in the direction of **steepest descent**

So if on the contour C' :

$$\phi(s) \equiv u + i \text{ const}$$

Example:

$$\phi(t) = t - \frac{t^3}{3}$$

$$\phi'(t) = 1 - t^2$$

$$\phi'(t) = 0 \implies t = \pm 1$$

So that means that $\xi = \pm 1$ So those are the saddle points.

We want a path that goes through $\xi = \pm 1$ and for

$$v(\xi, \eta) = \text{const}$$

$$\begin{aligned} \phi(t) &= \phi(\xi + i\eta) \\ &= \xi + i\eta - \frac{(\xi + i\eta)^3}{3} \\ &= \xi + i\eta - (\xi^3 + 3i\xi^2\eta - 3\xi\eta^2 - i\eta^3)/3 \\ &= \xi - \frac{1}{3}\xi^3 - \xi\eta^2 + i\left(\eta + \xi^2\eta - \frac{\eta^3}{3}\right) \end{aligned}$$

$$\begin{aligned} v &= \text{Im}(\phi) \\ &= \eta - \xi^2\eta + \frac{\eta^3}{3} \end{aligned}$$

At the saddle, $t = \pm 1$, so $\xi = \pm 1$ and $\eta = 0$

So curves of steepest descent (and ascent) will satisfy

$$0 = \eta(1 - \xi^2 - \eta^2)$$

There were some errors on the working but the idea was there.

$$\xi = \pm \sqrt{1 + \eta^2}$$

Methods of steepest descents is a process:

1. Find the saddle points and identify the **direction** of steepest descents
2. Deform contour to go through saddle point(s) in that direction of steepest descent
3. Evaluate the local contribution to the integral from the saddle
4. Evaluate any contributions from end points (if appropriate) - you may use steepest descent there as well. This means joining it to the path of steepest descent at the start and end of the integral (if it doesn't already)

The usual rules of contour integrals will still apply - we may need residue calculus (we will relearn that later) if poles are picked up in deforming the contour.

We don't actually always need saddles for this to work

Consider the integral.

$$I(x) = \int_0^1 \log t e^{ixt} dt$$

There is no point where $\phi'(t) = i = 0$, and integration by parts fails. How do we evaluate this integral?

Saddles aren't the only points with steepest descent paths - any point will have a path of steepest descent. The path of steepest descent will be increasing in η , and constant in ξ . So we want the path where we go in the direction positively in η around $\xi = 0$ and negatively in ξ . Let these paths go to a point $R \rightarrow \infty$ and then join the paths. Lets call the one that comes out of $(0, 0) \rightarrow (0, R) =: C_1$ $(0, R) \rightarrow (1, R) =: C_2$ and $(1, R) \rightarrow (1, 0) =: C_3$.

For C_1 the greatest contribution is around the start $0 \rightarrow 0 + \epsilon$, C_2 is 0 for sufficiently large R . On C_3 let $t = 1 + is$, and then the greatest contribution is around $s = 0$ So our integral becomes

$$\begin{aligned} I(x) &= \int_{C_1+C_2+C_3} \log t e^{ixt} dt \\ &= \int_{C_1} \log t e^{ixt} dt + \int_{C_2} \log t e^{ixt} dt + \int_{C_3} \log t e^{ixt} dt \end{aligned}$$

Denote the integrals as I_1, I_2, I_3 on C_1, C_2, C_3 respectively Since C_1 is only moving on the imaginary axis, we have $t = is$

$$\begin{aligned} I_1 &= \int_{C_1} \log t e^{ixt} dt \\ &= \int_0^R \log ise^{-xs} i ds \\ &= \int_0^\infty i \log ise^{-xs} ds \end{aligned}$$

Having let $R \rightarrow \infty$. Note this gets rid of the oscillations! We can now just use Laplace's method to evaluate the integral. But this one can be done normally

$$\begin{aligned} I_1 &= i \int_0^\infty \left(\log(s) + \frac{i\pi}{2} \right) e^{-xs} ds \\ &= -i \frac{\log x}{x} - (i\gamma + \pi/2)/x \end{aligned}$$

(hes not sure about the result there)

Where γ is Euler's constant. (Not sure how but apparently the first integral could be done exactly)

For I_2 plug in $t = iR + s$ and you find that it gets really small really quick (so its approximately 0)

For I_3 , $t = 1 + is$, but this parametrisation goes the wrong way, so we will have to introduce a minus sign.

$$\begin{aligned} I_3 &= \int_{C_3} \log t e^{ixt} dt \\ &= - \int_0^\infty \log(1 + is) e^{ix(1+is)} i ds \\ &= -ie^{ix} \int_0^\infty \log(1 + is) e^{-xs} ds \end{aligned}$$

This can't be evaluated exactly. Apply Watson's lemma Write $\log(1 + is)$ in a Taylor series

$$\log(1 + is) = - \sum_{n=1}^{\infty} \frac{(-is)^n}{n}$$

Using Watson's lemma gives the integrand is

$$I_3 \sim ie^{ix} \sum_{n=1}^{\infty} \frac{(-i)^n (n-1)!}{x^{n+1}}$$

As $x \rightarrow \infty$

Now we just add the bits together!

$$\begin{aligned} I &= I_1 + I_2 + I_3 \\ &\sim -i \frac{\log x}{x} - \frac{(i\gamma + \pi/2)}{x} + ie^{ix} \sum_{n=1}^{\infty} \frac{(-i)^n (n-1)!}{x^{n+1}} \end{aligned}$$
